Standard
ECMA-376

1st Edition / December 2006

Office Open XML File Formats

Office Open XML

Part 1: Fundamentals

December 2006

Table of Contents

Foreword

This multi-part Standard deals with Office Open XML Format-related technology, and consists of the following parts:

- **Part 1: "Fundamentals" (this document)**
- Part 2: "Open Packaging Conventions"
- Part 3: "Primer"
- Part 4: "Markup Language Reference"
- Part 5: "Markup Compatibility and Extensibility"

Parts 2 and 4 include a number of annexes that refer to data files provided in electronic form only.

Introduction

This Part is one piece of a Standard that describes a family of XML schemas, collectively called *Office Open XML*, which define the XML vocabularies for word-processing, spreadsheet, and presentation documents, as well as the packaging of documents that conform to these schemas.

The goal is to enable the implementation of the Office Open XML formats by the widest set of tools and platforms, fostering interoperability across office productivity applications and line-of-business systems, as well as to support and strengthen document archival and preservation, all in a way that is fully compatible with the large existing investments in Microsoft Office documents.

The following organizations have participated in the creation of this Standard and their contributions are gratefully acknowledged:

Apple, Barclays Capital, BP, The British Library, Essilor, Intel, Microsoft, NextPage, Novell, Statoil, Toshiba, and the United States Library of Congress

1. Scope

This Standard defines Office Open XML's vocabularies and document representation and packaging. It also specifies requirements for consumers and producers of Office Open XML.

2. Conformance

The text in this Standard is divided into *normative* and *informative* categories. Unless documented otherwise, any feature shall be implemented as specified by the normative text describing that feature in this Standard. Text marked informative (using the mechanisms described in §7) is for information purposes only. Unless stated otherwise, all text is normative.

Use of the word “shall” indicates required behavior.

Any behavior that is not explicitly specified by this Standard is implicitly unspecified (§4).

2.1 Goal

The goal of this clause is to define conformance, and to provide interoperability guidelines in a way that fosters broad and innovative use of the Office Open XML file format, while maximizing interoperability and preserving investment in existing files and applications (§4). By meeting this goal, this Standard benefits the following audiences:

- Developers that design, implement, or maintain Office Open XML applications.
- Developers that interact programmatically with Office Open XML applications.
- Governmental or commercial entities that procure Office Open XML applications.
- Testing organizations that verify conformance of specific Office Open XML applications to this Standard. (Note that this Standard does not include a test suite.)
- Educators and authors who teach about Office Open XML applications.

2.2 Issues

To achieve the above goal, the following issues need to be considered:

1. The application domain encompasses a range of possible consumers (§4) and producers (§4) so broad that defining specific application behaviors would restrict innovation. For example, stipulating visual layout would be inappropriate for a consumer that extracts data for machine consumption, or that renders text in sound. Another example is that restricting capacity or precision runs the risk of diluting the value of future advances in hardware.
2. Commonsense user expectations regarding the interpretation of an Office Open XML package (§4) play such an important role in that package's value that a purely syntactic definition of conformance would fail to effect a useful level of interoperability. For example, such a definition would admit an application that reads a package, and then writes it in a manner that, though syntactically valid, differs arbitrarily from the original.
3. Legitimate operations on a package include deliberate transformations, making blanket change prohibitions inappropriate in the conformance definition. For example, collapsing spreadsheet formulas to their calculated values, or converting complex presentation graphics to static bitmaps,

could be correct for an application whose published purpose is to perform those operations. Again, commonsense user expectation makes the difference.

4. Existing files and applications exercise a broad range of formats and functionality that, if required by the conformance definition, would add an impractical amount of bulk to the This Standard and could inadvertently obligate new applications to implement a prohibitive amount of functionality. This issue is caused by the breadth of currently available functionality and is compounded by the existence of legacy formats.

2.3 What this Standard Specifies

To address the issues listed above, this Standard constrains both syntax and semantics, but it is not intended to predefine application behavior. Therefore, it includes, among others, the following three types of information:

1. Schemas and an associated validation procedure for validating document syntax against those schemas. (The validation procedure includes un-zipping, locating files, processing the extensibility elements and attributes, and XML Schema validation.)
2. Additional syntax constraints in written form, wherever these constraints cannot feasibly be expressed in the schema language.
3. Descriptions of element semantics. The semantics of an element refers to its intended interpretation by a human being.

2.4 Document Conformance

Document conformance is purely syntactic; it involves only Items 1 and 2 in §2.3 above.

- A conforming document shall conform to the schema (Item 1) and any additional syntax constraints (Item 2).
- The document character set shall conform to the Unicode Standard and ISO/IEC 10646-1, with either the UTF-8 or UTF-16 encoding form, as required by the XML 1.0 standard.
- Any XML element or attribute not explicitly included in this Standard shall use the extensibility mechanisms described by Parts 4 and 5 of this Standard.

2.5 Application Conformance

Application conformance is purely syntactic; it also involves only Items 1 and 2 in §2.3 above.

- A conforming consumer shall not reject any conforming documents of the document type (§4) expected by that application.
- A conforming producer shall be able to produce conforming documents.

2.6 Interoperability Guidelines

[*Guidance*: The following interoperability guidelines incorporate semantics (Item 3 in §2.3 above).

For the guidelines to be meaningful, a software application should be accompanied by publicly available documentation that describes what subset of this Standard it supports. The documentation should highlight

any behaviors that would, without that documentation, appear to violate the semantics of document elements. Together, the application and documentation should satisfy the following conditions.

1. The application need not implement operations on all elements defined in this Standard. However, if it does implement an operation on a given element, then that operation should use semantics for that element that are consistent with this Standard.
2. If the application moves, adds, modifies, or removes element instances with the effect of altering document semantics, it should declare the behavior in its documentation.

The following scenarios illustrate these guidelines.

- A presentation editor that interprets the preset shape geometry "`rect`" as an ellipse does not observe the first guideline because it implements "`rect`" but with incorrect semantics.
- A batch spreadsheet processor that saves only computed values even if the originally consumed cells contain formulas, may satisfy the first condition, but does not observe the second because the editability of the formulas is part of the cells' semantics. To observe the second guideline, its documentation should describe the behavior.
- A batch tool that reads a word-processing document and reverses the order of text characters in every paragraph with "Title" style before saving it can be conforming even though this Standard does not anticipate this behavior. This tool's behavior would be to transform the title "Office Open XML" into "LMX nepO eciffO". Its documentation should declare its effect on such paragraphs. *end guidance*]

3. Normative References

The following normative documents contain provisions, which, through reference in this text, constitute provisions of this Standard. For dated references, subsequent amendments to, or revisions of, any of these publications do not apply. However, parties to agreements based on this Standard are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. For undated references, the latest edition of the normative document referred to applies. Members of ISO and IEC maintain registers of currently valid International Standards.

ISO/IEC 2382.1:1993, *Information technology — Vocabulary — Part 1: Fundamental terms*.

ISO/IEC 10646:2003 (all parts), *Information technology — Universal Multiple-Octet Coded Character Set (UCS)*.

4. Definitions

For the purposes of this Standard, the following definitions apply. Other terms are defined where they appear in *italic* type or on the left side of a syntax rule. Terms explicitly defined in this Standard are not to be presumed to refer implicitly to similar terms defined elsewhere. [*Note*: This part uses OPC-related terms, which are defined in Part 2: "Open Packaging Conventions". *end note*]

application — A consumer or producer.

behavior — External appearance or action.

behavior, implementation-defined — Unspecified behavior where each implementation documents that behavior, thereby promoting predictability and reproducibility within any given implementation. (This term is sometimes called “application-specific behavior”.)

behavior, locale-specific — Behavior that depends on local conventions of nationality, culture, and language.

behavior, unspecified —Behavior where this Standard imposes no requirements. [*Note*: To add an extension, an implementer must use the extensibility mechanisms described by this Standard rather than trying to do so by giving meaning to otherwise unspecified behavior. *end note*]

document type — One of the three types of Office Open XML documents: Wordprocessing, Spreadsheet, and Presentation, defined as follows:

- A document whose package-relationship item contains a relationship to a Main Document part (§11.3.10) is a document of type Wordprocessing.
- A document whose package-relationship item contains a relationship to a Workbook part (§12.3.23) is a document of type Spreadsheet.
- A document whose package-relationship item contains a relationship to a Presentation part (§13.3.6) is a document of type Presentation.

An Office Open XML document can contain one or more embedded Office Open XML packages (§15.2.10) with each embedded package having any of the three document types. However, the presence of these embedded packages does not change the type of the document.

DrawingML — A set of conventions for specifying the location and appearance of drawing elements in an Office Open XML document.

extension — Any XML element or attribute not explicitly included in this Standard, but that uses the extensibility mechanisms described by this Standard.

Office Open XML document — A package containing ZIP items as required by, and satisfying Parts 1 and 4 of, this Standard. A rendition of a data stream formatted using the wordprocessing, spreadsheet, or presentation ML and its related MLs as described in this Standard. Such a document is represented as a package.

package— A ZIP archive that conforms to the Open Packaging Conventions specification defined in Part 2 of this Standard.

package, embedded— A package that has been stored as the target of a valid Embedded Package relationship (§15.2.10) in an Office Open XML document

PresentationML — A set of conventions for representing an Office Open XML document of type Presentation.

relationship —The kind of connection between a source part and a target part in a package. Relationships make the connections between parts directly discoverable without looking at the content in the parts, and without altering the parts themselves. (See also Package Relationships.)

relationships part — A part containing an XML representation of relationships.

relationship, explicit — A relationship in which a resource is referenced from a source part's XML using the Id attribute of a Relationship tag.

relationship, implicit — A relationship that is not explicit.

SpreadsheetML — A set of conventions for representing an Office Open XML document of type Spreadsheet.

WordprocessingML — A set of conventions for representing an Office Open XML document of type Wordprocessing.

5. Notational Conventions

The following typographical conventions are used in this Standard:

1. The first occurrence of a new term is written in italics. [*Example*: … is considered *normative*. *end example*]
2. A term defined as a basic definition is written in bold. [*Example*: **behavior** — External … *end example*]
3. The name of an XML element is written using an Element style. [*Example*: The root element is document. *end example*]
4. The name of an XML element attribute is written using an Attribute style. [*Example*: … an id attribute. *end example*]
5. An XML element attribute value is written using a constant-width style. [*Example*: … value of `CommentReference`. *end example*]
6. An XML element type name is written using a Type style. [*Example*: … as values of the xsd:anyURI data type. *end example*]

6. Acronyms and Abbreviations

This clause is informative

The following acronyms and abbreviations are used throughout this Standard:

IEC — the International Electrotechnical Commission

ISO — the International Organization for Standardization

W3C — World Wide Web Consortium

End of informative text

7. General Description

This Standard is intended for use by implementers, academics, and application programmers. As such, it contains a considerable amount of explanatory material that, strictly speaking, is not necessary in a formal specification.

This Part is divided into the following subdivisions:

1. Front matter (clauses 1–7);
2. Overview (clause 8);
3. Main body (clauses 9–14);
4. Annexes

Examples are provided to illustrate possible forms of the constructions described. References are used to refer to related clauses. Notes are provided to give advice or guidance to implementers or programmers. Rationale provides explanatory material as to why something is or is not in this Standard. Annexes provide additional information or summarize the information contained in this Standard.

Clauses 1–5, 7, and 9–14 form a normative part of this Part; and the Introduction, clauses 6 and 8, as well as the annexes, notes, examples, rationale, guidance, and the index, are informative.

Except for whole clauses or annexes that are identified as being informative, informative text that is contained within normative text is indicated in the following ways:

1. [*Example:* code fragment, possibly with some narrative … *end example*]
2. [*Note:* narrative … *end note*]
3. [*Rationale:* narrative … *end rationale*]
4. [*Guidance*: narrative … *end guidance*]

8. Overview

This clause is informative.

This clause contains an overview of Office Open XML.

8.1 Packages and Parts

An Office Open XML document is represented as a series of related *parts* that are stored in a container called a *package*. Information about the *relationships* between a package and its parts is stored in the package's *package-relationship ZIP item*. Information about the *relationships* between two parts is stored in the *part-relationship ZIP item* for the source part. A package is an ordinary ZIP archive, which contains that package's content-type item, relationship items, and parts. (Packages are discussed further in Part 2.)

A WordprocessingML document contains a part for the body of the text; it might also contain a part for an image referenced by that text, and parts defining document characteristics, styles, and fonts. A SpreadsheetML document contains a separate part for each worksheet; it might also contain parts for images. A PresentationML document contains a separate part for each slide.

8.2 Consumers and Producers

A tool that can read and understand a package is called a *consumer*, while one that can create a package is called a *producer*. An application can be a consumer, a producer, or both. For example, when a word processor creates a new document, it acts as a producer. When it is used to open an existing document for reading or search purposes, it acts as a consumer. When it is used to open an existing document, edit it, and save the result, it acts as both consumer and producer. Similar scenarios exist for spreadsheet and presentation applications.

8.3 WordprocessingML

This subclause introduces the overall form of a WordprocessingML package, and identifies some of its main element types. (See Part 3 for a more detailed introduction.)

A WordprocessingML package has a relationship of type officeDocument, which specifies the location of the main part in the package. For a WordprocessingML document, that part contains the main text of the document.

A WordprocessingML package's main part starts with a word processing root element. That element contains a *body*, which, in turn, contains one or more *paragraphs* (as well as tables, pictures, and the like). A paragraph contains one or more runs, where a *run* is a container for one or more pieces of *text* having the same set of properties. Like many collection element types, each run and paragraph can have associated with it a set of *properties*. For example, a run might have the property bold, which indicates that run's text is to be displayed in a bold typeface.

A WordprocessingML document is organized into *sections*, and the layout of a page on which the text appears within a section is controlled by that section's properties. For example, each section can have its own *headers* and *footers*.

One relationship from the document part specifies the document's styles. A *style* defines a text display format. A style can have properties, which can be applied to individual paragraphs or runs. Styles make runs more compact by reducing the number of repeated definitions and properties, and the amount of work required to make changes to the document's appearance. With styles, the appearance of all the pieces of text that share a common style can be changed in one place, in that style's definition.

A series of paragraphs can have *numbering* applied to them via a numbering definition instance or a numbering style.

Data in a WordprocessingML document can be organized in a *table*, a two-dimensional grid of *cells* organized into *rows* and *columns*. Cells and whole tables can have associated properties. A cell can contain text and paragraphs, for example.

Text within a WordprocessingMLdocument can be determined dynamically via the use of *fields*. Fields consist of *field instructions* (the text that dictates the field's dynamic behavior) and the *field result* (the text resulting from the dynamic calculation of the field instructions. For example, page numbers are represented as fields. A *hyperlink* consists of two pieces of information: the hyperlink itself—the text the user will click—and the target for the link. Potential targets include external files, e-mail addresses, web sites, and bookmarks within the document itself.

A WordprocessingML document can also contain *custom markup*, user-defined semantics applied to arbitrary document content.

A WordprocessingML document is not stored as one large body in a single part; instead, the elements that implement certain groupings of functionality are stored in separate parts. For example, all footnotes in a document are stored in one footnote part, while each section can have up to three different header parts and three different footer parts, to support headers and footers on odd-numbered pages, even-numbered pages, and the first page.

8.4 SpreadsheetML

This subclause introduces the overall form of a SpreadsheetML package, and identifies some of its main element types. (See Part 3 for a more detailed introduction.)

A SpreadsheetML package has a relationship of type officeDocument, which specifies the location of the main part in the package. For a SpreadsheetML document, that part contains the workbook definition.

A SpreadsheetML package's main part starts with a spreadsheet root element. That element is a *workbook*, which refers to one or more *worksheets*, which, in turn, contain the data. A worksheet is a two-dimensional grid of *cells* that are organized into *rows* and *columns*.

The cell is the primary place in which data is stored and operated on. A cell can have a number of characteristics, such as numeric, text, date, or time *formatting*; *alignment*; *font*; *color*; and a *border*. Each cell is identified by a *cell reference*, a combination of its column and row headings.

Each horizontal set of cells in a worksheet is called a *row*, and each row has a heading numbered sequentially, starting at 1. Each vertical set of cells in a worksheet is called a *column*, and each column has an alphabetic heading named sequentially from A–Z, then AA–AZ, BA–BZ, and so on.

Instead of data, a cell can contain a *formula*, which is a recipe for calculating a value. Some formulas—called *functions*—are predefined, while others are user-defined. Examples of predefined formulas are `AVERAGE`, `MAX`, `MIN`, and `SUM`. A function takes one or more arguments on which it operates, producing a result. For example, in the formula `SUM(B1:B4)`, there is one argument, `B1:B4`, which is the range of cells B1–B4, inclusive.

Other features that a SpreadsheetML document can contain include the following: *comments*, *hyperlinks*, *images*, and sorted and filtered *tables*.

A SpreadsheetML document is not stored as one large body in a single part; instead, the elements that implement certain groupings of functionality are stored in separate parts. For example, all the data for a worksheet is stored in that worksheet's part, all string literals from all worksheets are stored in a single shared string part, and each worksheet having comments has its own comments part.

8.5 PresentationML

This subclause introduces the overall form of a PresentationML package, and identifies some of its main element types. (See Part 3 for a more detailed introduction.)

A PresentationML package has a relationship of type officeDocument, which specifies the location of the main part in the package. For a PresentationML document, that part contains the presentation definition.

A PresentationML package's main part starts with a presentation root element. That element contains a *presentation*, which, in turn, refers to a *slide* list, a *slide master* list, a *notes master* list, and a *handout master* list. The slide list refers to all of the slides in the presentation; the slide master list refers to all of the slide masters used in the presentation; the notes master contains information about the formatting of notes pages; and the handout master describes how a handout looks.

A *handout* is a printed set of slides that can be handed out to an *audience* for future reference.

As well as text and graphics, each slide can contain *comments* and *notes*, can have a *layout*, and can be part of one or more *custom presentations*. (A comment is an annotation intended for the person maintaining the presentation slide deck. A note is a reminder or piece of text intended for the presenter or the audience.)

Other features that a PresentationML document can contain include the following: *animation*, *audio*, *video*, and *transitions* between slides.

A PresentationML document is not stored as one large body in a single part; instead, the elements that implement certain groupings of functionality are stored in separate parts. For example, all comments in a document are stored in one comment part while each slide has its own part.

8.6 Supporting MLs

This subclause introduces the set of markup languages used across package types. (See Part 3 for a more detailed introduction.)

The three markup languages described above define the structure of a package that is either a document (WordprocessingML), a spreadsheet (SpreadsheetML), or a presentation (PresentationML). However, there is also a set of shared markup languages used for common elements such as charts, diagrams, and drawing objects. These MLs are discussed below.

8.6.1 DrawingML

DrawingML specifies the location and appearance of drawing elements in a package. For example, these elements could be, but are not limited to, shapes, pictures, and tables. The root element of a DrawingML XML fragment specifies the presence of a drawing at this location in the document.

A *shape* is a geometric object such as a circle, square, or rectangle; a *picture* is an image presented inside the document; and a *table* is a two-dimensional grid of *cells* organized into *rows* and *columns*. Cells and whole tables can have associated properties. A cell can contain text, for example.

DrawingML also specifies the location and appearance of charts in a package. The root element of a chart part is chart, and specifies the appearance of the chart at this location in the document.

In addition, DrawingML specifies package-wide appearance characteristics, such as the package's theme. The *theme* of a document specifies the *color scheme*, *fonts*, and *effects*, which can be referenced by parts of the document—such as text, drawings, charts, and diagrams—in order to create a consistent visual presentation.

A *chart* is a presentation of data in a graphical fashion, such as a pie chart, bar chart, line chart, in order to make trends and exceptions in the data more visually apparent.

DrawingML also specifies the location and appearance of diagrams in a document. Together, the following four parts define a diagram:

- The *data* part (§14.2.4) specifies individual items of information presented in the diagram. Typically, each piece is a simple line of text, but depending on the diagram, an item of data might also be an image.
- The *layout* part (§14.2.5) specifies how the data and shapes are laid out to create the resulting diagram.
- The *colors* part (§14.2.3) specifies the color which is applied to each individual shape in the diagram.
- The *styles* part (§14.2.6) defines how each individual shape in the diagram maps to the document's theme.

8.6.2 VML

VML specifies the appearance and content of certain shapes in a document. This is used for shapes such as text boxes, as well as shapes which must be stored to maintain compatibility with earlier versions of consumer/producer applications.

[*Note*: The VML format is a legacy format originally introduced with Office 2000 and is included and fully defined in this Standard for backwards compatibility reasons. The DrawingML format is a newer and richer format created with the goal of eventually replacing any uses of VML in the Office Open XML formats. VML should be considered a deprecated format included in Office Open XML for legacy reasons only and new applications that need a file format for drawings are strongly encouraged to use preferentially DrawingML. *end note*]

A shape definition is typically specified using two elements: shapeData, which stores information about the shape, and shape, which stores the shape definition and appearance directly.

8.6.3 Custom XML Data Properties

Custom XML Data properties allow the ability to store arbitrary XML in a package, along with schema information used by that XML.

8.6.4 File Properties

The *core file properties* of a package enable users to discover, get, and set common sets of properties from within that package, regardless of whether it's a WordprocessingML, SpreadsheetML, or PresentationML package, or another use of OPC. Such properties include creator name, creation date, title, and description.

Extended file properties are specific to Office Open XML packages. For example, for a WordprocessingML package, these properties include the number of characters, words, lines, paragraphs, and pages in the document. For a SpreadsheetML package, these properties include worksheet titles. For a PresentationML package, these properties include presentation format, the number of slides, the number of notes, and whether or not any slides are hidden.

Custom file properties are defined by the user. Examples include the name of the client for whom the document was prepared, a date/time on which some event happened, a document number, or some Boolean status flag. Each custom file property has a value, and that value has a type.

8.6.5 Math

Math specifies the structure and appearance of equations in a document; it is specified with a root element of math.

8.6.6 Bibliography

Bibliography specifies the structure for all references stored within a document, for use in citations or a bibliography.

End of informative text.

9. Packages

An Office Open XML document is stored as a package, whose format is defined by Part 2: "Open Packaging Conventions". This subclause contains information regarding Office Open XML's use of OPC.

Throughout this Standard, the Open Packaging Conventions are referred to by their abbreviated name, OPC.

9.1 Constraints on Office Open XML's Use of OPC

While the OPC specification is designed for the representation of Office Open XML documents, it could also support a much broader range of applications. As a result, the use of some OPC features is restricted within Office Open XML documents. These additional requirements are discussed in the following subordinate subclauses. Any requirement not mentioned here is inherited from the OPC specification.

9.1.1 Part Names

An Office Open XML part name shall contain only ASCII characters, in non-escaped or escaped form. The following ASCII characters are permitted in non-escaped form: "!", "$", "%", "&", "'", "(", ")", "*", "+", ",", "-", ".", the decimal digits "0"–"9", ":", ";", "=", "@", the Latin alphabetic characters "A"–"Z" and "a"–"z", "_", and "~". All other ASCII characters are permitted only when escaped as an encoded triplet of the form "%HH", where H is a hexadecimal digit.]

9.1.2 Part Addressing

Parts in an Office Open XML package targeted by relationships are addressed in relationship markup through part names. External document resources targeted by a relationship can be addressed using both relative and absolute references.

9.1.3 Fragments

Fragment identifiers are supported as part of all Office Open XML external relationship targets and some Office Open XML internal relationship targets.

9.1.4 Physical Packages

Each Office Open XML document is implemented as a ZIP archive.

9.1.5 Interleaving

Office Open XML document parts shall be arranged contiguously in a package as defined by simple ordering.

Parts within an Office Open XML package shall not be interleaved. All parts shall be stored as complete ZIP items, and the interleaving functionality defined in Part 2 of this Standard shall not be used. [*Note*: Part 2 of this Standard specifies a method for interleaving parts, which is a very useful capability for stream processing. In order to simplify initial implementations of the Standard, interleaving is not used in this current version of

the Office Open XML formats but it may be used in further versions of the standard or by other formats that leverage OPC. *end note*]

9.1.6 Unknown Parts

With the exception of relationship parts, all other parts in an Office Open XML document that are not the target of a valid relationship are considered *unknown parts*. Unknown parts shall be ignored on document consumption and can, but need not, be discarded on production.

9.1.7 Trash Items

Trash items represent parts that have been discarded or are no longer in use. Trash items shall not conform to OPC part naming guidelines as defined in Part 2 and shall not be associated with a content type. All trash items shall follow the naming scheme: `[trash]/hhhh.dat` where h represents a hexadecimal value.

[*Example*: A package has two parts that must be updated in-place but both parts have grown beyond their growth hints. The newer updated parts are added as new ZIP items while the original parts are renamed to:

```
[trash]/0000.dat
[trash]/0001.dat
```

end example]

9.1.8 Invalid Parts

ZIP archive items that do not conform to OPC part naming guidelines or are not associated with a content type shall not be allowed in an Office Open XML document, with the exception of items specifically defined by Part 2: “Open Packaging Conventions” and trash items.

9.1.9 Unknown Relationships

All relationships not defined within this Standard are considered *unknown relationships*. Unknown relationships are valid within an Office Open XML document provided that they conform to relationship markup guidelines as defined by the OPC specification. Specifically:

- Conforming consumers shall not fail to load a document containing unknown relationships.
- Conforming producers are encouraged to roundtrip and preserve unknown relationships and their target parts.

9.2 Relationships in Office Open XML

In OPC, relationships describe references from parts to other internal resources in the package or to external resources. They represent the type of connection between a source part and a target resource, and make the connection directly discoverable without looking at the part contents, so they are quick to resolve.

The same ZIP item can be the target of multiple relationships. [*Note*: Having multiple paths to a target can make access to that target more convenient. *end note*]

Office Open XML imposes constraints on relationships, described in subsequent clauses of this part. Relationships in Office Open XML are either explicit or implicit.

For an explicit relationship, a resource is referenced from a source part's XML using the Id attribute of a Relationship tag. [*Example*: A document part can have a relationship to a hyperlink only if that hyperlink's Relationship element's Id attribute value is referenced explicitly by the document part's XML. *end example*] [*Note*: Because this mechanism is used generically across multiple tag types, explicit relationships can be extracted from an Office Open XML document without prior knowledge of tag semantics. *end note*]. Certain relationships shall be *explicit*.. All other relationships are *implicit* [*Note*: The syntax for specifying an implicit relationship varies among tag types. *end note*]. Relationships that are required or permitted, and restrictions on those relationships are described in §10–15 of this Part.

[*Example*: Consider a WordprocessingML document that contains the following footnote sentence fragment, "… produced by Ecma[1] (http://www.ecma-international.org/).", which contains a footnote and a hyperlink to a web site. The relationship from a source to a footnote is implicit while that to a hyperlink is explicit.

The Main Document part's relationship file contains the following:

```
<Relationships …>
  <Relationship Id="rId5" Type="…/footnotes"
    Target="footnotes.xml"/>
  <Relationship Id="rId7" Type="…/hyperlink"
    Target="http://www.ecma-international.org/" TargetMode="External"/>
</Relationships>
```

All footnotes for a WordprocessingML document are contained in the same Footnotes part. Let's look at how the Main Document refers to the footnote. At the point at which the footnote reference is inserted, the following XML is present:

```
<w:r>
      <w:footnoteReference w:id="2"/>
</w:r>
```

The w:id="2" refers to the footnote with id=2 in the Footnotes part, the relevant piece of which is:

```
<w:footnote w:id="2">
  …
  Ecma is an international standards development organization (SDO).
  …
</w:footnote>
```

In the case of the hyperlink, the main document part makes an explicit reference to this relationship when it refers to the hyperlink, by using the following:

```
<w:hyperlink r:id="rId7" w:history="1">
  …
</w:hyperlink>
```

The important distinction here is that there is no explicit reference to a relationship ID designating the Footnotes part. The reference to the footnote with `id=2` is “understood” to be in the Footnotes part that must always exist if there are any footnotes in the document. *end example*]

[*Example*: The following figure shows how the source, relationship item, and the target relate to each other for implicit and explicit relationships, respectively. The target does not have to be a file, however.

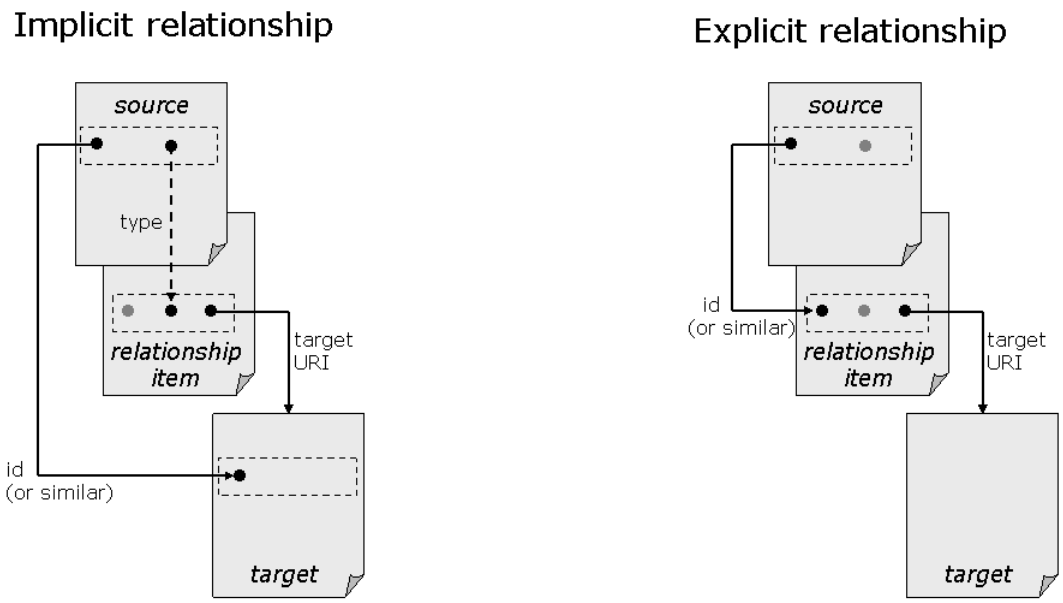
The dots correspond to attributes of relevant elements. Where one attribute refers to a piece in another part, this is indicated by arrows. Solid arrows indicate that the value of the source directly corresponds to the value at the target (for instance, id=rId4 in the source part corresponds to id=rId4 in the relationship item).

Dotted arrows indicate that the value of the source only implicit corresponds to the value of the target (for instance, "footnoteReference" in the source indicates the type "footnotes" in the relationship item).

The main difference between the two types of relationship is that for implicit relationships, the id of the reference refers to an element with the same id in the target part, whereas for explicit relationships, the id refers to a relationship with the same id in the relationship item.

Both relationship types use the target URI of the relationship in the relationship item to locate the target.

For explicit relationships, the id in the source XML links to a relationship item with a direct explicit reference to the target. For implicit relationships, the relationship item is implied by the containing tag (e.g., footnote) and the id in the source XML is used to locate the correct element within the implied target.



1

2 *end example*]

3 [*Example*: The following figure shows the implicit relationship for the footnote example described earlier.

Example Implicit relationship

2 *end example*]

10. Markup Compatibility and Extensibility

Office Open XML documents are designed to allow for innovation by extending their capabilities via a scheme defined by Part 5: "Markup Compatibility and Extensibility". This subclause contains information regarding Office Open XML's use of the Markup Compatibility constructs.

10.1 Constraints on Office Open XML's Use of Markup Compatibility and Extensibility

While the Markup Compatibility and Extensibility specification is designed for and used by Office Open XML documents, it could also be used to support a much broader range of applications. As a result, the use of some Markup Compatibility and Extensibility features is restricted within Office Open XML documents. These additional requirements are discussed in the following subordinate subclauses. Any requirement not mentioned here is inherited from the Markup Compatibility and Extensibility specification.

10.1.1 PreserveElements and PreserveAttributes

The PreserveElements and PreserveAttributes elements, as defined in Part 5, allow a markup language to specify the conditions under which extensions should be round-tripped, even when their contents are edited. Within the context of the markup languages explicitly defined by this Standard, no such conditions are specified, and therefore applications are not obliged to support these hints at any point in an Office Open XML document. Instead, the well-defined extensibility constructs defined below should be used.

All other constructs defined in Part 5 shall be supported.

10.1.2 Office Open XML Native Extensibility Constructs

Clause 12 of Part 5 specifies the ability for a markup language to define additional constructs for extensibility of a specific markup language. Within the context of Office Open XML documents, the extLst element(s) defined in individual markup languages shall allow the round-tripping of all unknown content regardless of the state of the PreserveElements and PreserveAttributes elements. See Part 4 for additional information on the valid use of the extLst construct.

11. WordprocessingML

This clause contains specifications for relationship items and parts that are specific to WordprocessingML. Parts that can occur in a WordprocessingML document, but are not WordprocessingML-specific, are specified in §15.2. Unless stated explicitly, all references to relationship items, content-type items, and parts in this clause refer to WordprocessingML ZIP items.

11.1 Glossary of WordprocessingML-Specific Terms

The following terms are used in the context of a WordprocessingML document:

comment — A note that an author or reviewer attaches to a piece of text in a document. Although a consumer may chose to display comments, they are not considered part of the body of the document. A comment includes the text of the note, the comment author's name and initials, and date of creation, among other things.

document setting — A reusable element in a template. [*Note*: Such elements include boilerplate text, cover pages, equations, footers, headers, tables, text boxes, and watermarks. *end note*]

glossary document — An additional WordprocessingML document story used to store reusable fragments of rich WordprocessingML content. It is called the glossary document as this story contains one or more fragments that can be indexed and extracted by name, like items in a glossary.

master document — A document that is the parent of one or more subdocuments. [*Note*: A master document can be used to manage a multipart document, such as a book having several chapters. In such as case, the master document might contain the cover page, front matter, table of contents, and cross-reference index, while each chapter and appendix resides in its own subdocument. *end note*]

section — A portion of a document in which certain page formatting options can be set. [*Note*: A new section is created to change such properties as line numbering, number of columns, or headers and footers. *end note*]

subdocument — A piece of a master document. [*Note*: A chapter or appendix might be a subdocument in a book. *end note*]

supplementary document storage location — A part within a WordprocessingML document in which fragments of WordprocessingML content can be stored separate from the printed page. See also **glossary document**

template — A document that is a pattern for creating other documents. A template can contain text, formatting, and graphics, among other things, such that documents based on it automatically have access to these elements.

11.2 Package Structure

A WordprocessingML package shall contain a package-relationship item and a content-type item. The package-relationship item shall contain implicit relationships with targets of the following type:

- One Main Document part (§11.3.10)

The package-relationship item is permitted to contain implicit relationships with targets of the following type:

- Digital Signature Origin (§15.2.6)
- File Property parts (§15.2.11) (Application-Defined File Properties, Core File Properties, and Custom File Properties), as appropriate.
- Thumbnail (§15.2.14).

The required and optional relationships between parts are defined in §11.3 and its subordinate clauses.

[*Example*: The following package represents the minimal conformant WordprocessingML package as defined by this Standard:

First, the content type for relationship parts and the Main Document part (the only required part) must be defined (physically located at /[Content_Types].xml in the package):

```
<Types xmlns="…">
  <Default Extension="rels"
    ContentType="application/vnd.openxmlformats-
      package.relationships+xml"/>
  <Override PartName="/document.xml"
    ContentType="application/vnd.openxmlformats-
      officedocument.wordprocessingml.document.main+xml"/>
</Types>
```

Next, the single required relationship (the package-level relationship to the Main Document part) must be defined (physically located at /_rels/.rels in the package):

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://schemas.openxmlformats.org/officeDocument/2006/
      relationships/officeDocument"
    Target="document.xml"/>
</Relationships>
```

Finally, the minimum content for the Main Document part must be defined (physically located at /document.xml in the package):

```
<w:document xmlns:w="…">
  <w:body>
    <w:p/>
  </w:body>
</w:document>
```

end example]

[*Example*: Consider a WordprocessingML document that is an early draft of this Standard. Here's an example of the hierarchical folder structure that might be used for the ZIP items in the package for that document. As shown, one part, Main Document (stored in the ZIP item /word/document.xml), has its own relationship item:

```
/[Content_Types].xml        Content-type item
/_rels/.rels                      Package-relationship item
/docProps/app.xml                 Application-Defined File Properties part
/docProps/core.xml                Core File Properties part
/word/document.xml                Main Document part
/word/_rels/document.xml.rels     Part-relationship item
/word/comments.xml                Comment part
/word/endnotes.xml                Endnotes part
/word/fontTable.xml               Font Table part
/word/footer1.xml                 Footer parts
/word/footer2.xml
/word/footer3.xml
/word/footer4.xml
/word/footnotes.xml               Footnotes part
/word/header1.xml                 Header parts
/word/header2.xml
/word/header3.xml
/word/header4.xml
/word/header5.xml
/word/header6.xml
/word/numbering.xml               Numbering Definitions part
/word/settings.xml                Document Settings part
/word/styles.xml                  Style Definitions part
/word/theme/theme1.xml            Theme part
```

The package-relationship item contains the following:

```
<Relationships xmlns="…">
  <Relationship Id="rId3"
    Type="http://…/extended-properties" Target="docProps/app.xml"/>
  <Relationship Id="rId2"
    Type="http://…/core-properties" Target="docProps/core.xml"/>
```

```
    <Relationship Id="rId1"
      Type="http://…/officeDocument" Target="word/document.xml"/>
  </Relationships>
```

end example]

11.3 Part Summary

The subclauses subordinate to this one describe in detail each of the part types specific to WordprocessingML. [*Note*: For convenience, information from those subclauses is summarized in the following table:

Part	Relationship Target of	Root Element	Ref.
Alternative Format Import	Comments, Endnotes, Footer, Footnotes, Header, or Main Document	Not applicable	§11.3.1
Comments	Glossary Document or Main Document	comments	§11.3.2
Document Settings	Glossary Document or Main Document	settings	§11.3.3
Endnotes	Glossary Document or Main Document	endnotes	§11.3.4
Font Table	Glossary Document or Main Document	fonts	§11.3.5
Footer	Glossary Document or Main Document	ftr	§11.3.6
Footnotes	Glossary Document or Main Document	footnotes	§11.3.7
Glossary Document	Main Document	glossaryDocument	§11.3.8
Header	Glossary Document or Main Document	hdr	§11.3.9
Main Document	WordprocessingML package	document	§11.3.10
Numbering Definitions	Glossary Document or Main Document	numbering	§11.3.11
Style Definitions	Glossary Document or Main Document	styles	§11.3.12
Web Settings	Glossary Document or Main Document	webSettings	§11.3.13

end note]

11.3.1 Alternative Format Import Part

Content Type:	Any content, support for which is application-defined. [*Note*: Some examples of formats which might be supported include: • Text = application/txt • RTF = application/rtf • HTML = application/html • XML = application/xml *end note*]
Root Namespace:	not applicable
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/aFChunk

An alternative format import part allows content specified in an alternate format (HTML, MHTML, RTF, earlier versions of WordprocessingML, or plain text) to be embedded directly in a WordprocessingML document in order to allow that content to be migrated to the WordprocessingML format.

Any document part that permits a p element can also contain an altChunk element, whose id attribute refers to a relationship. That relationship shall target a part within the package, which contains the content to be imported into this WordprocessingML document.

A package is permitted to contain zero or more Alternative Format Import parts, each of which shall have a corresponding alternate format file that is the target of an explicit relationship from a Comments (§11.3.2), Endnotes (§11.3.4), Footer (§11.3.6), Footnotes (§11.3.7), Header (§11.3.9), or Main Document (§11.3.10) part. This relationship shall be explicitly referenced using its relationship ID in the source part using the appropriate XML syntax (i.e.; in the id attribute on the altChunk element), and the presence of this relationship without such a reference shall be considered invalid.

A WordprocessingML consumer shall treat the contents of such legacy text files as if they were formatted using equivalent WordprocessingML, and if that consumer is also a WordprocessingML producer, it shall emit the legacy text in WordprocessingML format.

This Standard does not specify how one might create a WordprocessingML package that contains Alternative Format Import relationships and altChunk elements.

However, a conforming producer shall not create a WordprocessingML package that contains Alternative Format Import relationships and elements. [*Note*: The Alternative Format Import machinery provides a one-time conversion facility. A producer could have an extension that allows it to generate a package containing these relationships and elements, yet when run in conforming mode, does not do so. *end note*]

[*Example*: The following Main Document part-relationship item contains a relationship to an Alternative Format Import part:

```
<Relationships xmlns="…">
  <Relationship Id="rId5"
    Type="http://…/aFChunk" Target="Demo.html"
    TargetMode="Internal"/>
</Relationships>
```

The Main Document part contains the following XML fragment:

```
<w:body>
  …
  <w:p/>
  <w:altChunk r:id="rId5"/>
  <w:p/>
  …
</w:body>
```

which results in the entire contents of Demo.html being converted and brought into the document at that point (assuming that the content type of Demo.html is supported by the application consuming this WordprocessingML file). *end example*]

An Alternative Format Import part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

An Alternative Format Import part shall not have any explicit or implicit relationships to parts defined by this Standard.

11.3.2 Comments Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.comments+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/comments

An instance of this part type contains the information about each comment in the document.

A package shall contain no more than two Comments parts. If it exists, one instance of that part shall be the target of an implicit relationship from the Main Document (§11.3.10) part, and the other shall be the target of an implicit relationship from the Glossary Document (§11.3.8) part.

[*Example*: The following Main Document part-relationship item contains a relationship to the Contents part, which is stored as the ZIP item comment.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId93"
    Type="http://…/comments" Target="comments.xml"/>
</Relationships>
```

end example]

The root element for a Comment part shall be comments.

[*Example*:

```
<w:comments … >
  <w:comment>
    …
  </w:comment>
  …
</w:comments>
```

end example]

The XML markup for a comment in a Main Document part uses the commentReference element.

[*Example*: Consider the case in which the Main Document part contains the text "… in the Standard.", and there is an comment inserted immediately after the period:

```
<w:p …>
  …
  <w:r>
    <w:t>... in the Standard.</w:t>
  </w:r>
  <w:r>
    <w:commentReference w:id="1"/>
  </w:r>
</w:p>
```

end example]

Each comment has a corresponding comment element in the Comments part, which contains the text of the comment.

[*Example*: The text of the comment is "This is my comment.":

```
<w:comments xmlns:w="…"
  <w:comment w:id="1">
    <w:p>
      <w:r>
        <w:t>This is my comment.</w:t>
    </w:p>
  </w:comment>
</w:comments>
```

end example]

A Comments part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Comments part is permitted to contain explicit relationships to the following parts defined by this Standard:

- Alternative Format Import (§11.3.1)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlinks (§15.3)
- Images (§15.2.13)
- Video (§15.2.16)

A Comments part shall not have any implicit or explicit relationships to any other part defined by this Standard.

11.3.3 Document Settings Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.settings+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/settings

An instance of this part type contains all the document's properties.

A package shall contain no more than two Document Settings parts. If it exists, one instance of that part shall be the target of an implicit relationship from the Main Document (§11.3.10) part, and the other shall be the target of an implicit relationship from the Glossary Document (§11.3.8) part.

[*Example*: The following Main Document part-relationship item contains a relationship to a Document Settings part, which is stored in the ZIP item documentProperties1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/settings" Target="settings.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be settings.

[*Example*:

```
<w:settings … >
  …
  <w:defaultTabStop w:val="360"/>
  <w:footnotePr>
    …
  </w:footnotePr>
  <w:endnotePr>
  …
  </w:endnotePr>
  <w:rsids>
  …
  </w:rsids>
  …
</w:settings>
```

end example]

A Document Settings part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Document Settings part is permitted to contain explicit relationships to the following parts defined by this Standard:

- Document Template (§11.4)
- Mail Merge Data Source (§11.7)
- Mail Merge Header Data Source (§11.8)
- XSL Transformation (§11.9)

A Document Settings part shall not have any implicit or explicit relationships to any other part defined by this Standard.

11.3.4 Endnotes Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.endnotes+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/endnotes

An instance of this part type contains all the endnotes for the document.

A package shall contain no more than two Endnotes parts. If it exists, one instance of that part shall be the target of an implicit relationship from the Main Document (§11.3.10) part, and the other shall be the target of an implicit relationship from the Glossary Document (§11.3.8) part.

[*Example*: The following Main Document part-relationship item contains a relationship to the Endnotes part, which is stored as the ZIP item endnotes.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId6"
    Type="http://…/endnotes" Target="endnotes.xml"/>
</Relationships>
```

end example]

The root element for an Endnotes part shall be endnotes.

[*Example*:

```
<w:endnotes xmlns:w="…" …>
  <w:endnote …>
    …
  </w:endnote>
  <w:endnote …>
    …
  </w:endnote>
</w:endnotes>
```

end example]

The XML markup for an endnote in a Main Document part uses the endnoteReference element.

[*Example*: Consider the case in which the Main Document part contains the text "… in the Standard.", and there is an endnote inserted immediately after the period:

```
<w:p …>
  …
  <w:r>
    <w:t>... in the Standard.</w:t>
  </w:r>
  <w:r>
    <w:rPr>
      <w:rStyle w:val="EndnoteReference"/>
    </w:rPr>
    <w:endnoteReference w:id="5"/>
  </w:r>
</w:p>
```

end example]

Each endnote has a corresponding endnote element in the Endnotes part, which contains the text of the endnote, and the endnoteRef element.

[*Example*: The text of the endnote is "This can be downloaded from http://www.aabbcc.com/index.html." where "http://www.aabbcc.com/index.html" is marked as a hyperlink:

```
<w:endnotes xmlns:w="…">
  <w:endnote w:id="5">
    <w:p>
      <w:r>
        <w:rPr>
          <w:rStyle w:val="EndnoteReference"/>
        </w:rPr>
        <w:endnoteRef/>
      </w:r>
      <w:r>
        <w:t xml:space="preserve"> This can be downloaded from </w:t>
      </w:r>
      <w:hyperlink r:id="rId2">
        <w:r>
          <w:rPr>
            <w:rStyle w:val="Hyperlink"/>
          </w:rPr>
          <w:t>http://www.aabbcc.com/index.html</w:t>
        </w:r>
      </w:hyperlink>
```

```
          <w:r>
            <w:t>.</w:t>
        </w:p>
      </w:endnote>
    </w:endnotes>
```

end example]

An Endnotes part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

An Endnotes part is permitted to contain explicit relationships to the following parts defined by this Standard:

- Alternative Format Import (§11.3.1)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlinks (§15.3)
- Images (§15.2.13)
- Video (§15.2.16)

An Endnotes part shall not have any implicit or explicit relationships to any other part defined by this Standard.

11.3.5 Font Table Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.fontTable+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/fontTable

An instance of this part type contains information about each of the fonts used by content in the document. When a consumer reads a WordprocessingML document, it shall use this information to determine which fonts to use to display the document when the specified fonts are not available on the consumer's system.

A package shall contain no more than two Font Table parts. If it exists, one instance of that part shall be the target of an implicit relationship in the part-relationship item for the Main Document (§11.3.10) part, and the other instance shall be the target of an implicit relationship from the Glossary Document (§11.3.8) part.

[*Example*: The following Main Document part-relationship item contains a relationship to the Font Table part, which is stored as the ZIP item fontTable.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/fontTable" Target="fontTable.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be fonts.

[*Example*:

```
<w:fonts … >
  <w:font w:name="Calibri">
    <w:panose1 w:val="020F0502020204030204"/>
    <w:charset w:val="00"/>
    <w:family w:val="swiss"/>
    <w:pitch w:val="variable"/>
    <w:sig w:usb0="A00002EF" w:usb1="4000207B" w:usb2="00000000"
      w:usb3="00000000" w:csb0="0000009F" w:csb1="00000000"/>
  </w:font>
</w:fonts>
```

end example]

A Font Table part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Font Table part is permitted to contain explicit relationships to the following parts defined by this Standard:

- Fonts (§15.2.12)

A Font Table part shall not have any implicit or explicit relationships to any other part defined by this Standard.

11.3.6 Footer Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.footer+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer

An instance of this part type contains the information about a footer displayed for one or more sections.

A package is permitted to contain zero or one Footer part for each kind of footer (first page, odd page, or even page) in each section of the document. Each Footer part shall be the target of an explicit relationship in the part-relationship item for the Main Document (§11.3.10) part, or the Glossary Document (§11.3.8) part.

[*Example*: The Main Document part-relationship item contains one relationship, for the odd footer part, which is stored as the ZIP item footer3.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId91"
    Type="http://…/footer" Target="footer3.xml"/>
</Relationships>
```

end example]

The root element for a Footer part type shall be ftr.

[*Example*:

```
<w:ftr xmlns:w="…" …>
  …
</w:ftr>
```

end example]

The XML markup for a footer in a section of a Main Document part involves the footerReference element in that section's sectPr element which explicitly references the relationship for the header.

[*Example*: Consider the case in which a section in the Main Document part contains odd and even headers, and an odd footer:

```
<w:document xmlns:w="…">
  …
  <w:sectPr>
    <w:footerReference w:val="rId89" w:type="default"/>
    <w:footerReference w:val="rId90" w:type="even"/>
    <w:footerReference w:val="rId91" w:type="first"/>
    <w:type w:val="oddPage"/>
    <w:pgSz w:w="11909" w:h="16834" w:code="9"/>
    <w:pgMar w:top="1440" w:right="1152" w:bottom="1440"
      w:left="1152" w:header="720" w:footer="720" w:gutter="0"/>
    <w:lnNumType w:countBy="1"/>
    <w:pgNumType w:numFmt="lowerRoman"/>
    <w:cols w:space="720"/>
  </w:sectPr>
</w:document>
```

end example]

Each footer has a corresponding ftr element in a Footer part, which contains the text of the footer.

[*Example*: Here is the odd footer corresponding to the example above. It has the page number centered and displayed using lowercase Roman numerals (as set by the pgNumType element above):

```
<w:ftr xmlns:w="…">
  <w:p>
    <w:pPr>
      <w:pStyle w:val="Centered"/>
    </w:pPr>
    <w:fldSimple w:instr="PAGE">
      <w:r>
        <w:rPr>
          <w:noProof/>
        </w:rPr>
        <w:t>i</w:t>
      </w:r>
    </w:fldSimple>
  </w:p>
</w:ftr>
```

end example]

A Footer part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Footer part is permitted to have explicit relationships to the following parts defined by this Standard:

- Alternative Format Import (§11.3.1)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlinks (§15.3)
- Images (§15.2.13)
- Video (§15.2.16)

A Footer part shall not have any implicit or explicit relationships to any other part defined by this Standard.

11.3.7 Footnotes Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.footnotes+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/footnotes

An instance of this part type contains all the footnotes for the document.

A package shall contain no more than two Footnotes parts. If it exists, one instance of that part shall be the target of an implicit relationship from the Main Document (§11.3.10) part, and the other shall be the target of an implicit relationship from the Glossary Document (§11.3.8) part.

[*Example*: The Main Document part-relationship item contains a relationship to the Footnotes part, which is stored as the ZIP item footnotes.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId5"
    Type="http://…/footnotes" Target="footnotes.xml"/>
</Relationships>
```

end example]

The root element for a Footnotes part shall be footnotes.

[*Example*:

```
<w:footnotes xmlns:w="…" …>
  <w:footnote …>
    …
  </w:footnote>
  <w:footnote …>
    …
  </w:footnote>
</w:footnotes>
```

end example]

The XML markup for a footnote in a Main Document part involves the footnoteReference element.

[*Example*: Consider the case in which the Main Document part contains the text "… in the Standard.", and there is a footnote inserted immediately after the period:

```
<w:p …>
  …
  <w:r>
    <w:t>... in the Standard.</w:t>
  </w:r>
  <w:r>
    <w:rPr>
      <w:rStyle w:val="FootnoteReference"/>
    </w:rPr>
    <w:footnoteReference w:id="5"/>
  </w:r>
</w:p>
```

end example]

Each footnote has a corresponding footnote element in the Footnotes part, which contains the text of the footnote and the footnoteRef element.

[*Example*: The text of the footnote is "This can be downloaded from http://www.aabbcc.com/index.html." where "http://www.aabbcc.com/index.html" is marked as a hyperlink:

```
<w:footnotes xmlns:w="…"
  <w:footnote w:id="5">
    <w:p>
      <w:r>
        <w:rPr>
          <w:rStyle w:val="FootnoteReference"/>
        </w:rPr>
        <w:footnoteRef/>
      </w:r>
      <w:r>
        <w:t xml:space="preserve">This can be downloaded from </w:t>
      </w:r>
      <w:hyperlink r:id="rId2" w:history="1">
        <w:r>
          <w:rPr>
            <w:rStyle w:val="Hyperlink"/>
          </w:rPr>
          <w:t>http://www.aabbcc.com/index.html</w:t>
        </w:r>
      </w:hyperlink>
```

```
          <w:r>
            <w:t>.</w:t>
          </w:r>
        </w:p>
      </w:footnote>
    </w:footnotes>
```

end example]

A Footnotes part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Footnotes part is permitted to have explicit relationships to the following parts defined by this Standard:

- Alternative Format Import (§11.3.1)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlinks (§15.3)
- Images (§15.2.13)
- Video (§15.2.16)

A Footer part shall not have any implicit or explicit relationships to any other part defined by this Standard.

11.3.8 Glossary Document Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.document.glossary+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/glossaryDocument

An instance of this part type is a supplementary document storage location which stores the definition and content for content that shall be carried with the document for future insertion and/or use, but which shall not be visible within the contents of the main document story. [*Example*: A legal contract template might include one or more optional clauses that shall not appear in the document until those clauses are inserted explicitly via a user action. To store these optional clauses until they are inserted, their contents are placed in the glossary document part. *end example*]

[*Note*: This part is intended for storage of optional "document fragments" which are often used to perform document assembly. The use of the word *glossary* is a reference to the fact that each of these entries was

historically referenced by its first word in legacy word processing applications, like definitions of terms in a traditional glossary. *end note*]

The root element for a part of this content type shall be glossaryDocument.

[*Example*: The following part contains two building blocks. The first block is named "rainbow colors", belongs to a category called "Misc", belongs to a gallery called "docParts", and contains the text "The colors … and violet." The details of the second block have been omitted:

```
<w:glossaryDocument xmlns:w="…" >
  <w:docParts>
    <w:docPart>
      <w:docPartPr>
        <w:name w:val="rainbow colors"/>
        <w:style w:val="Normal"/>
        <w:category>
          <w:name w:val="Misc"/>
          <w:gallery w:val="docParts"/>
        </w:category>
      </w:docPartPr>
      <w:docPartBody>
        <w:p>
          <w:r>
            <w:t>The colors of the rainbow are red, orange, yellow,
              green, blue, indigo, and violet.</w:t>
          </w:r>
        </w:p>
      </w:docPartBody>
    </w:docPart>
    <w:docPart>
      …
    </w:docPart>
  </w:docParts>
</w:glossaryDocument>
```

end example]

A package shall contain at most one Glossary Document part, and that part shall be the target of an implicit relationship from the Main Document (§11.3.10) part.

[*Example*: The following Main Document part-relationship item contains a relationship to a Glossary Document part, which is stored in the ZIP item `glossary/document.xml`:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/glossaryDocument" Target="glossary/document.xml"/>
</Relationships>
```

end example]

A Glossary Document part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Glossary Document part is permitted to have implicit relationships to the following parts defined by this Standard:

- Comments (§11.3.2)
- Document Settings (§11.3.3)
- Endnotes (§11.3.4)
- Font Table (§11.3.5)
- Footnotes (§11.3.7)
- Numbering Definitions (§11.3.11)
- Style Definitions (§11.3.11)

A Glossary Document part is permitted to have explicit relationships to the following parts defined by this Standard:

- Alternative Format Import (§11.3.1)
- Chart (§14.2.1)
- Diagrams: Diagram Colors (§14.2.3), Diagram Data (§14.2.4), Diagram Layout Definition (§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Footer (§11.3.6)
- Header (§11.3.9)
- Hyperlinks (§15.3)
- Images (§15.2.13)
- Printer Settings (§15.2.14)
- Video (§15.2.16)

A Glossary Document part shall not have implicit or explicit relationships to any other part defined by this Standard.

11.3.9 Header Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.header+xml

Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/header

An instance of this part type contains the information about a header displayed for one or more sections.

A package shall contain zero or one Header part for each kind of header (first page, odd page, or even page) in each section of the document. Each Header part shall be the target of an explicit relationship from the Main Document (§11.3.10) part or the Glossary Document (§11.3.8) part.

[*Example*: The Main Document part-relationship item contains two relationships: one for the even header part (which is stored as the ZIP item header2.xml) and one for the odd header part (which is stored as the ZIP item header3.xml):

```
<Relationships xmlns="…">
  <Relationship Id="rId89" Type="http://…/header" Target="header2.xml"/>
  <Relationship Id="rId90" Type="http://…/header" Target="header3.xml"/>
</Relationships>
```

end example]

The root element for a Header part shall be hdr.

[*Example*:

```
<w:hdr xmlns:w="…" …>
  …
</w:hdr>
```

end example]

The XML markup for a header in a section of a Main Document part involves the headerReference element in that section's sectPr element.

[*Example*: Consider the case in which a section in the Main Document part contains odd and even headers, and an odd footer:

```
<w:body>
  …
  <w:sectPr w:rsidR="00363F31" w:rsidSect="008D4B40">
    <w:headerReference w:val="rId89" w:type="default"/>
    <w:headerReference w:val="rId90" w:type="even"/>
    <w:headerReference w:val="rId91" w:type="first"/>
    <w:type w:val="oddPage"/>
    <w:pgSz w:w="11909" w:h="16834" w:code="9"/>
    <w:pgMar w:top="1440" w:right="1152" w:bottom="1440"
      w:left="1152" w:header="720" w:footer="720" w:gutter="0"/>
    <w:lnNumType w:countBy="1"/>
    <w:pgNumType w:fmt="lowerRoman"/>
    <w:cols w:space="720"/>
  </w:sectPr>
</w:body>
```

end example]

Each header has a corresponding hdr element in a Header part, which contains the text of the header.

[*Example*: Here is the even header corresponding to the examples above:

```
<w:hdr xmlns:w="…">
  <w:p>
    <w:pPr>
      <w:pStyle w:val="Header"/>
    </w:pPr>
    <w:r>
      <w:t>My Test Document</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

Here is the odd header corresponding to the examples above:

```
<w:hdr xmlns:w="…">
  <w:p>
    <w:pPr>
      <w:pStyle w:val="Header"/>
    </w:pPr>
    <w:r>
      <w:tab/>
      <w:t>Table of Contents</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

end example]

A Header part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Header part is permitted to have explicit relationships to the following parts defined by this Standard:

- Alternative Format Import (§11.3.1)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlinks (§15.3).
- Images (§15.2.13)
- Video (§15.2.16)

A Header part shall not have any implicit or explicit relationships to other parts defined by this Standard.

11.3.10 Main Document Part

Content Type(s):	application/vnd.openxmlformats-officedocument.wordprocessingml.main+xml application/vnd.openxmlformats-officedocument.wordprocessingml.template.main+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/officeDocument

An instance of this part type contains the body of the document.

A package shall contain a Main Document part (§11.3.10) part. The Main Document part shall be the target of a relationship in the package-relationship item.

The root element for a part of this content type shall be document.

[*Example*: Given the following package-relationship item excerpt:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/officeDocument" Target="word/document.xml"/>
</Relationships>
```

/word/document.xml" contains the following:

```
<w:document …>
  <w:body>
    …
  </w:body>
</w:document>
```

end example]

A Main Document part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Main Document part is permitted to have implicit relationships to the following parts defined by this Standard:

- Additional Characteristics (§15.2.1)
- Bibliography (§15.2.3)
- Comments (§11.3.2)
- Custom XML Data Storage (§15.2.4)
- Document Settings (§11.3.3)
- Endnotes (§11.3.4)
- Font Table (§11.3.5)
- Footnotes (§11.3.7)
- Glossary Document (§11.3.8)
- Numbering Definitions (§11.3.11)
- Style Definitions (§11.3.12)
- Theme (§14.2.7)
- Thumbnail (§15.2.14)

A Main Document part is permitted to contain explicit relationships to the following parts defined by this Standard:

- Alternative Format Import (§11.3.1)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Footer (§11.3.6)
- Header (§11.3.9)
- Hyperlinks (§15.3)
- Images (§15.2.13)
- Printer Settings (§15.2.14)
- Subdocument (§11.6)
- Video (§15.2.16)

A Main Document shall not have implicit or explicit relationships to any other part defined by this Standard.

11.3.11 Numbering Definitions Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.numbering+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/numbering

An instance of this part type contains a definition for the structure of each unique numbering definition in this document.

[*Example:* If a set of paragraphs are added to a document which have a circle bullet at the first level, a square bullet at the second level, and a checkmark bullet at the third level, such as the following:

- First level
  - Second level
    - ✓ Third level

The numbering definition part will contain the definition for each of these levels (their bullet style, indent, etc.) even if the second and third levels are not actually used in the document *end example*]

A package shall contain no more than two Numbering Definitions parts. If they exist, one instance of that part shall be the target of an implicit relationship from the Main Document (§11.3.10) part, and the other shall be the target of an implicit relationship from the Glossary Document (§11.3.8) part.

[*Example*:

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/numbering" Target="numbering.xml"/>
</Relationships>
```

end example]

The XML markup for a list usage involves a reference to a numbering definition via the child elements of the numPr element.

[*Example*: Here we have a paragraph set using the style `Text`, followed by a list of things which have the paragraph style `ListBullet`, followed by another paragraph set using the style `Text`:

```
<w:p>
  <w:pPr>
    <w:pStyle w:val="Text"/>
  </w:pPr>
  <w:r>
    <w:t>The kinds of fruit needed are:</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:pStyle w:val="ListBullet"/>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Apples</w:t>
  </w:r>
</w:p>
```

```
    <w:p>
      <w:pPr>
        <w:pStyle w:val="ListBullet"/>
        <w:numPr>
          <w:ilvl w:val="0" />
          <w:numId w:val="5" />
        </w:numPr>
      </w:pPr>
      <w:r>
        <w:t>Oranges</w:t>
      </w:r>
    </w:p>
    <w:p>
      <w:pPr>
        <w:pStyle w:val="Text"/>
      </w:pPr>
      <w:r>
        <w:t>Other items may be needed too.</w:t>
      </w:r>
    </w:p>
```

end example]

The root element for a Numbering Definition part shall be numbering, with each numbering definition being defined by an abstractNum element.

[*Example*:

```
    <w:numbering xmlns:w="…">
      <w:abstractNum w:numId="11">
        <w:nsid w:val="394E2425"/>
        <w:multiLevelType w:val="hybridMultilevel"/>
        <w:tmpl w:val="F628E89A"/>
        <w:lvl w:ilvl="0" w:tplc="151C4798">
          <w:start w:val="1"/>
          <w:numFmt w:val="bullet"/>
          <w:pStyle w:val="ListBullet"/>
          <w:lvlText w:val="…"/>
          <w:lvlJc w:val="left"/>
          <w:pPr>
            <w:tabs>
              <w:tab w:val="list" w:pos="720"/>
            </w:tabs>
            <w:ind w:left="720" w:hanging="360"/>
          </w:pPr>
```

```
          <w:rPr>
            <w:rFonts w:ascii="Symbol" w:hAnsi="Symbol" w:hint="default"/>
          </w:rPr>
        </w:lvl>
        …
      </w:abstractNum>
    </w:numbering>
```

end example]

A Numbering Definitions part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Numbering Definitions part is permitted to contain explicit relationships to the following parts defined by this Standard:

- Images (§15.2.13)

A Numbering Definitions part shall not have any implicit or explicit relationships to any other part defined by this Standard.

11.3.12 Style Definitions Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.styles+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/styles

An instance of this part type contains the definition for a set of styles used by this document.

A package shall contain at most two Style Definitions parts. One instance of that part shall be the target of an implicit relationship from the Main Document (§11.3.10) part, and the other shall be the target of an implicit relationship in from the Glossary Document (§11.3.8) part.

[*Example*:

```
  <Relationships xmlns="…">
    <Relationship Id="rId3"
      Type="http://…/styles" Target="styles.xml"/>
  </Relationships>
```

end example]

The root element for a Styles Definition part shall be styles, which is a container for one or more style elements.

[*Example*: Here is the style `ListBullet` (which is used in a Main Document Part in §11.3.10):

```
<w:styles xmlns:wx="…" xmlns:w="…" … xml:space="preserve">
  <w:style w:type="paragraph" w:styleId="ListBullet">
    <w:name w:val="List Bullet"/>
    <w:basedOn w:val="Text"/>
    <w:autoRedefine/>
    <w:rsid w:val="00081289"/>
    <w:pPr>
      <w:pStyle w:val="ListBullet"/>
      <w:numPr>
        <w:numId w:val="1"/>
      </w:numPr>
      <w:tabs>
        <w:tab w:val="clear" w:pos="360"/>
      </w:tabs>
      <w:ind w:left="648"/>
    </w:pPr>
  </w:style>
</w:styles>
```

end example]

A Style Definitions part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Style Definitions part shall not have implicit or explicit relationships to any part defined by this Standard.

11.3.13 Web Settings Part

Content Type:	application/vnd.openxmlformats-officedocument.wordprocessingml.webSettings+xml
Root Namespace:	http://schemas.openxmlformats.org/wordprocessingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/webSettings

An instance of this part type contains the definition for web-specific settings used by this document.

A package shall contain at most two Web Settings parts. One instance of that part shall be the target of an implicit relationship from the Main Document (§11.3.10) part, and the other shall be the target of an implicit relationship from the Glossary Document (§11.3.8) part.

[*Example*:

```
<Relationships xmlns="…">
  <Relationship Id="rId3"
    Type="http://…/webSettings" Target="webSettings.xml"/>
</Relationships>
```

end example]

The root element for a Web Settings part shall be webSettings.

[*Example*:

```
<w:webSettings …>
  <w:frameset>
    …
    <w:frame>
      <w:sz w:val="216" />
      <w:name w:val="Frame2" />
      <w:sourceFileName r:id="rId1" />
    </w:frame>
    <w:frame>
      <w:name w:val="Frame1" />
      <w:sourceFileName r:id="rId2" />
    </w:frame>
  </w:frameset>
</w:webSettings>
```

end example]

A Web Settings part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Web Settings part is permitted to contain explicit relationships to the following parts defined by this Standard:

- Frameset (§11.5)

A Web Settings part shall not contain implicit or explicit relationships to any other part defined by this Standard.

11.4 Document Template

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/attachedTemplate

A *document template* can be represented by an instance of a WordprocessingML package, and contains styles, numbering definitions, and so on that are made available when documents based on that template are edited.

A WordprocessingML document can refer to another document as its document template, by having a Document Settings part (§11.3.3) that contains an explicit relationship to the file location of the necessary document template using the id attribute on the attachedTemplate element.

[*Example*: Consider a document specifying a document template located at `c:\template.docx`:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/attachedTemplate" Target="file:///c:\template.docx"
    TargetMode="External"/>
</Relationships>
```

The document's Document Settings part contains an attachedTemplate element that explicitly references this relationship:

```
<w:settings … >
  <w:attachedTemplate r:id="rId1"/>
</w:settings>
```

end example]

11.5 Framesets

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/frame

A *frameset* is a WordprocessingML document which specifies the location and placement of other WordprocessingML documents (which, when used in this context, are referred to as *frames*). A frameset shall be represented by an instance of a WordprocessingML document with a Web Settings part (§11.3.13) whose relationship item targets each of that frameset's frames.

[*Example*: Consider a frameset document having two frames. The frameset's Web Settings part-relationships item contains the following, in which frame1.docx and frame2.docx are packages containing the corresponding frames:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/frame" Target="frame1.docx" TargetMode="External"/>
  <Relationship Id="rId2"
    Type="http://…/frame" Target="frame2.docx" TargetMode="External"/>
</Relationships>
```

The frameset document's Web Settings part contains a frameset element that references its frames:

```
<w:webSettings …>
  <w:frameset>
    …
    <w:frame>
      <w:sz w:val="216" />
      <w:name w:val="Frame2" />
      <w:sourceFileName r:id="rId1" />
    </w:frame>
    <w:frame>
      <w:name w:val="Frame1" />
      <w:sourceFileName r:id="rId2" />
    </w:frame>
  </w:frameset>
</w:webSettings>
```

end example]

A frame shall be represented by an instance of a WordprocessingML package.

A frame shall be located external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `External`).

11.6 Master Documents and Subdocuments

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/subDocument

A master document shall be represented by an instance of a WordprocessingML document whose Main Document (§11.3.10) part targets each of that master document's subdocuments.

[*Rationale*: Sometimes, it is convenient to deal with a document as a collection of pieces, especially when those pieces might be edited by different authors in a collaborative group. Perhaps it simply makes sense to think about a book as a collection of chapters rather than as one big document. The breaking-up of a document into such pieces can be achieved by having a master document with one or more subdocuments. *end rationale*]

[*Example*: Consider a master document, whose three subdocuments are called Start, Middle, and End, respectively. Master's Main Document part has a corresponding relationships part that contains the following, in which Start.docx, Middle.docx, and End.docx are packages containing the corresponding subdocuments:

```
<Relationships xmlns="…">
  <Relationship Id="rId5"
    Type="http://…/subDocument"
    Target="Start.docx" TargetMode="External"/>
```

```
    <Relationship Id="rId6"
      Type="http://…/SubDocument"
      Target="Middle.docx" TargetMode="External"/>
    <Relationship Id="rId7"
      Type="http://…/SubDocument"
      Target="End.docx" TargetMode="External"/>
  </Relationships>
```

The master document's Main Document part contains subDoc elements that reference its subdocuments:

```
  <w:document xmlns:r="…" xmlns:wx="…" …>
    <w:body>
      <w:p …>
        <w:pPr>
          …
        </w:pPr>
      </w:p>
      <w:subDoc r:id="rId5"/>
      …
      <w:subDoc r:id="rId6"/>
      …
      <w:subDoc r:id="rId7"/>
      …
    </w:body>
  </w:document>
```

end example]

A subdocument shall be represented by an instance of a WordprocessingML package.

A subdocument shall be located external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `External`).

11.7 Mail Merge Data Source

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/mailMergeSource

A document that stores information about a mail merge operation is permitted to contain a Document Settings part (§11.3.3) whose relationship item targets the file location of the necessary data source using this relationship.

[*Example*: Consider a document specifying a mail merge whose data source is located at `http://www.openxmlformats.org/data.txt`:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/mailMergeSource"
    Target="http://www.openxmlformats.org/data.txt"
    TargetMode="External"/>
</Relationships>
```

The document's Document Settings part contains a dataSource element that explicitly references this relationship:

```
<w:settings …>
  <w:mailMerge>
    …
    <w:dataSource r:id="rId1" />
    …
  </w:mailMerge>
</w:settings>
```

end example]

A mail merge data source shall be located external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `External`).

11.8 Mail Merge Header Data Source

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/mailMergeHeaderSource

A document that stores information about a mail merge operation is permitted to contain a Document Settings part (§11.3.3) whose relationship item targets the file location of the necessary header data source using this relationship.

[*Example*: Consider a document specifying a mail merge whose header data source is located at `http://www.openxmlformats.org/header.txt`:

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/mailMergeHeaderSource"
    Target=http://www.openxmlformats.org/header.txt
    TargetMode="External"/>
</Relationships>
```

The document's Document Settings part contains a headerSource element that explicitly references this relationship:

```
<w:settings …>
  <w:mailMerge>
    …
    <w:headerSource r:id="rId2" />
    …
  </w:mailMerge>
</w:settings>
```

end example]

A mail merge header data source shall be located external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `External`).

11.9 XSL Transformation

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/transform

A document can store information about an XSL Transformation which might be applied on save, by containing a Document Settings part (§11.3.3) whose part relationship item contains an explicit relationship to the file location of the XSL Transformation using this relationship.

[*Example*: Consider a document specifying an XSL Transformation located at `http://www.openxmlformats.org/test.xsl`:

```
<Relationships xmlns="…">
  <Relationship Id="rId8" Type="http://…/transform"
    Target="http://www.openxmlformats.org/test.xsl"
    TargetMode="External"/>
</Relationships>
```

The document's Document Settings part contains a saveThroughXslt element that explicitly references this relationship:

```
<w:settings …>
  …
  <w:saveThroughXslt r:id="rId8" />
  …
</w:settings>
```

end example]

An XSL transformation shall be located external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `External`).

12. SpreadsheetML

This clause contains specifications for relationship items and parts that are specific to SpreadsheetML. Parts than can occur in a SpreadsheetML document, but are not SpreadsheetML-specific, are specified in §15.2. Unless stated explicitly, all references to relationship items, content-type items, and parts in this clause refer to SpreadsheetML ZIP items.

12.1 Glossary of SpreadsheetML-Specific Terms

The following terms are used in the context of a SpreadsheetML document:

cell — The location at the intersection of a row and column, in which numeric or textual data or a formula is stored. A cell can have a number of characteristics, such as numeric or text formatting, alignment, font, color, and border.

cell reference — An individual cell's designation using a combination of its column and row headings, as in A13, H19, and BX1200. A **relative cell reference** in a formula automatically changes when the formula is copied down a column or across a row. An **absolute cell reference** is fixed. Absolute references don't change when a formula is copied from one cell to another. A **mixed cell reference** has either an absolute column and a relative row, or an absolute row and a relative column.

chart — A graphical representation of data, as in a bar, column, line, pie chart, for example.

column — Any vertical set of cells in a worksheet. Each column has an alphabetic heading. Columns are named sequentially, going from A–Z, then AA–AZ, BA–BZ, and so on.

comment — A reminder or annotation that can be attached to a cell.

connection — The means by which external data—that is, data stored outside of a workbook (in a database or on a Web server, for example)—can be imported into a worksheet.

formula — A recipe for calculating a value. Some formulas are predefined; others are user-defined.

function — A predefined formula, such as AVERAGE, MAX, MIN, and SUM. A function takes one or more arguments on which it operates, producing a result. [*Note*: In the formula =SUM(B1:B4), there is one argument, B1:B4, which is the range of cells B1–B4, inclusive. *end note*]

pivot table — A kind of table that is used to manage and analyze related data that is stored elsewhere.

row — Any horizontal set of cells in a worksheet. Each row has a numeric heading. Rows are numbered sequentially, starting at 1.

table — A rectangular-shaped set of related rows and columns that can be sorted, filtered, and totaled as a group. Rows in a table can be hidden by applying **autofilters** to one or more columns.

workbook — A collection of worksheets.

worksheet — A two-dimensional grid of cells that are organized into rows and columns.

12.2 Package Structure

A SpreadsheetML package shall contain a package-relationship item and a content-type item. The package-relationship item shall contain implicit relationships with targets of the following type:

- One Workbook part (12.3.23).

The package-relationship item is permitted to contain implicit relationships with targets of the following type:

- Digital Signature Origin (§15.2.6)
- File Property parts (§15.2.11) (Application-Defined File Properties, Core File Properties, and Custom File Properties), as appropriate.
- Thumbnail (§15.2.14).

The required and optional relationships between parts are defined in §12.3 and its subordinate clauses.

[*Example*: The following package represents the minimal conformant SpreadsheetML package as defined by this Standard:

First, the content types for relationship parts, the Workbook part, and at least one Sheet part must be defined (physically located at /[Content_Types].xml in the package):

```
<Types xmlns="…">
  <Default Extension="rels"
   ContentType="application/vnd.openxmlformats-package.relationships+xml"
   />
  <Override PartName="/workbook.xml"
   ContentType="application/vnd.openxmlformats-officedocument.
   spreadsheetml.sheet.main+xml" />
  <Override PartName="/sheet1.xml"
   ContentType="application/vnd.openxmlformats-
   officedocument.spreadsheetml.worksheet+xml" />
</Types>
```

Next, the required package-level relationship to the Workbook part must be defined (physically located at /_rels/.rels in the package):

```
<Relationships xmlns="…">
```

```
    <Relationship Id="rId1"
     Type=http://schemas.openxmlformats.org/officeDocument/2006/
     relationships/officeDocument"
     Target="workbook.xml" />
  </Relationships>
```

Next, the minimum content for the Workbook part must be defined (physically located at /workbook.xml in the package):

```
  <workbook xmlns="…" xmlns:r="…">
    <sheets>
      <sheet name="1" sheetId="1" r:id="rId1" />
    </sheets>
  </workbook>
```

Next, the required workbook-level relationship to the single Sheet part must be defined, (physically located at /_rels/workbook.xml.rels in the package):

```
  <Relationships xmlns="…">
    <Relationship Id="rId1"
     Type="http://schemas.openxmlformats.org/officeDocument/2006/
     relationships/worksheet" Target="sheet1.xml" />
  </Relationships>
```

Finally, the minimum content for a single Sheet part must be defined (physically located at /sheet1.xml in the package):

```
  <worksheet xmlns="…" xmlns:r="…">
    <sheetData />
  </worksheet>
```

end example]

[*Example*: Consider a SpreadsheetML document that contains a workbook having three worksheets. Here's an example of the hierarchical folder structure that might be used for the ZIP items in the package for that document. As shown, one part, Workbook (stored in the ZIP item /xl/workbook.xml), has its own relationship item:

```
  /_rels/.rels                    Package-relationship item
  /[Content_Types].xml            Content-type item
  /docProps/app.xml               Application-Defined File Properties part
  /docProps/core.xml              Core File Properties part
  /xl/workbook.xml                Workbook part
  /xl/_rels/workbook.xml.rels     Part-relationship item
```

```
/xl/calcChain.xml                Calculation Chain part
/xl/sharedStrings.xml            Shared String Table part
/xl/styles.xml                   Styles part
/xl/volatileDependencies.xml     Volatile Dependencies part
/xl/theme/theme1.xml             Theme part
/xl/worksheets/sheet1.xml        Worksheet parts
/xl/worksheets/sheet2.xml
/xl/worksheets/sheet3.xml
```

The package-relationship item contains the following:

```
<Relationships xmlns="…">
  <Relationship Id="rId3"
    Type="http://…/extended-properties" Target="docProps/app.xml"/>
  <Relationship Id="rId2"
    Type="http://…/core-properties" Target="docProps/core.xml"/>
  <Relationship Id="rId1"
    Type="http://…/officeDocument" Target="xl/workbook.xml"/>
</Relationships>
```

end example]

12.3 Part Summary

The subclauses subordinate to this one describe in detail each of the part types specific to SpreadsheetML. [*Note*: For convenience, information from those subclauses is summarized in the following table:

Part	Relationship Target of	Root Element	Ref.
Calculation Chain	Workbook	calcChain	§12.3.1
Chartsheet	Workbook	chartsheet	§12.3.2
Comments	Chartsheet, Dialogsheet, Worksheet	comments	§12.3.3
Connections	Workbook	connections	§12.3.4
Custom Property	Workbook	Not applicable	§12.3.5
Custom XML Mappings	Workbook	mapInfo	§12.3.6
Dialogsheet	Workbook	dialogSheet	§12.3.7
Drawings	Chartsheet, Worksheet	wsDr	§12.3.8
External Workbook References	Workbook	externalReference	§12.3.9
Metadata	Workbook	metadata	§12.3.10
Pivot Table	Worksheet	pivotTableDefinition	§12.3.11

Part	Relationship Target of	Root Element	Ref.
Pivot Table Cache Definition	Pivot Table, Workbook	pivotCacheDefinition	§12.3.12
Pivot Table Cache Records	Pivot Table Cache Definition	pivotCacheRecords	§12.3.13
Query Table	Worksheet	queryTable	§12.3.14
Shared String Table	Workbook	sst	§12.3.15
Shared Workbook Revision Headers	Workbook	headers	§12.3.16
Shared Workbook Revision Log	Shared Workbook Revision Headers	revisions	§12.3.17
Shared Workbook User Data	Workbook	users	§12.3.18
Single Cell Table Definitions	Dialogsheet, Worksheet	singleCells	§12.3.19
Styles	Workbook	styleSheet	§12.3.20
Table Definition	Dialogsheet, Worksheet	table	§12.3.21
Volatile Dependencies	Workbook	volTypes	§12.3.22
Workbook	SpreadsheetML package	workbook	§12.3.23
Worksheet	Workbook	worksheet	§12.3.24

end note]

12.3.1 Calculation Chain Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.calcChain+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/calcChain

An instance of this part type contains an ordered set of references to all cells in all worksheets in the workbook whose value is calculated from any formula. The ordering allows inter-related cell formulas to be calculated in the correct order when a worksheet is loaded for use.

A package shall contain no more than one Calculation Chain part. If it exists, that part shall be the target of an implicit relationship from the Workbook part (§12.3.23).

[*Example*: The following Workbook part-relationship item contains a relationship to the Calculation Chain part, which is stored in the ZIP item calcChain.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId7"
    Type="http://…/calcChain" Target="calcChain.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be calcChain.

[*Example*: Cells D8, E8, and F8 each contain a value that is the result of calculations that shall be performed in the order E8, D8, F8:

```
<calcChain xmlns="…">
  <c r="E8" i="1"/>
  <c r="D8"/>
  <c r="F8" s="1"/>
</calcChain>
```

end example]

A Calculation Chain part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Calculation Chain part shall not have implicit or explicit relationships to any part defined by this Standard.

12.3.2 Chartsheet Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.chartsheet+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/chartsheet

An instance of this part type represents a chart that is stored in its own sheet.

A package is permitted to contain zero or more Chartsheet parts. Each such part shall be the target of an explicit relationship from the Workbook part (§12.3.23).

[*Example*: The following Workbook part-relationship item contains three relationships to Chartsheet parts, which are stored in the ZIP items chartsheets/sheet*N*.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/chartsheet" Target="chartsheets/sheet1.xml"/>
  <Relationship Id="rId5"
    Type="http://…/chartsheet" Target="chartsheets/sheet2.xml"/>
  <Relationship Id="rId6"
    Type="http://…/chartsheet" Target="chartsheets/sheet3.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be chartsheet.

[*Example*: sheet1.xml refers to a drawing that is the target of a relationship in the Chartsheet part's relationship item:

```
<chartsheet xmlns:r="…" …>
  <sheetViews>
    <sheetView scale="64"/>
  </sheetViews>
  <drawing r:id="rId1"/>
</chartsheet>
```

end example]

A Chartsheet part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Chartsheet part is permitted to have implicit relationships to the following parts defined by this Standard:

- Printer Settings (§15.2.14)

A Chartsheet part is permitted to have explicit relationships to the following parts defined by this Standard:

- Drawings (§12.3.8)

A Chartsheet part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.3 Comments Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.comments+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/comments

An instance of this part type contains all the comments for a given worksheet, as well as the names of the authors of those comments.

A package shall contain exactly one Comments part for each worksheet that contains one or more comments. If a Comments part exists, it shall be the target of an implicit relationship from the Workbook part (§12.3.23).

[*Example*: The following Worksheet part-relationship item contains a relationship to the Comments part, which is stored in the ZIP item comments2.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/comments" Target="../comments2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be comments.

[*Example*: This Comments part results from a workbook that has one or more comments from each of two people: James Jones and Mary Smith:

```
<comments xmlns:st="…" >
  <authors>
    <author>James Jones</author>
    <author>Mary Smith</author>
  </authors>
  <commentList>
    <comment r="C7" authorId="0">
      <text>
        <st:r>
          <st:rPr>
            …
          </st:rPr>
          <st:t>James Jones:</st:t>
        </st:r>
        <st:r>
          <st:rPr>
            …
          </st:rPr>
          <st:t>Check that this date is correct.</st:t>
        </st:r>
      </text>
    </comment>
```

```
      <comment r="E7" authorId="1">
        …
      </comment>
    </commentList>
  </comments>
```

end example]

A Comments part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Comments part shall not implicit or explicit relationships to any part defined by this Standard.

12.3.4 Connections Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.connections+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/connections

An instance of this part type describes all of the connections currently established for a workbook.

A package shall contain no more than one Connections part, and that part shall be the target of an implicit relationship from the Workbook part (§12.3.23).

[*Example*: The following Workbook part-relationship item contains a relationship to the Connections part, which is stored in the ZIP item connections.xml:

```
  <Relationships xmlns="…">
    <Relationship Id="rId5"
      Type="http://…/connections" Target="connections.xml"/>
  </Relationships>
```

end example]

The root element for a part of this content type shall be connections.

[*Example*: A workbook has three connections, two from one worksheet, and one from another. connections.xml defines these three connections:

```
<connections …>
  <connection id="1" odcFile="…" keepAlive="1" name="…" type="5"
    refreshedVersion="2" background="1" saveData="1">
    <dbPr connection="Provider=MSDASQL.1;Persist Security Info=True;Data
Source=dBASE Files;Extended Properties=&quot;DSN=dBASE Files;DBQ=E:\MY
DOCUMENTS;DefaultDir=E:\MY
DOCUMENTS;DriverId=533;MaxBufferSize=2048;PageTimeout=5;&quot;;Initial
Catalog=E:\MY DOCUMENTS" command="`E:\MY DOCUMENTS`\`ADDRESS`"
commandType="3"/>
  </connection>
  <connection id="2" …>
    <dbPr … />
  </connection>
  <connection id="3" …>
    <dbPr … />
  </connection>
</connections>
```

end example]

A Connections part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Connections part shall not have implicit or explicit relationships to any part defined by this Standard..

12.3.5 Custom Property Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.customProperty
Root Namespace:	Not applicable
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/customProperty

This binary part supports the storage of arbitrary user-defined data.

A package shall contain at most one Custom Property part, and that part shall be the target of an implicit relationship from the Workbook (§12.3.23) part.

[*Example*: The following Workbook part-relationship item contains a relationship to the Custom Property part, which is stored in the ZIP item CustomProperty.bin:

```
<Relationships xmlns="…">
  <Relationship Id="rId7"
    Type="http://…/customProperty" Target="CustomProperty.bin"/>
</Relationships>
```

end example]

A Custom Property part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Custom Property part shall not have implicit or explicit relationships to any part defined by this Standard.

12.3.6 Custom XML Mappings Part

Content Type:	application/xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/xmlMaps

An instance of this part type contains a schema for an XML file, and information on the behavior that is used when allowing this custom XML schema to be mapped into the spreadsheet.

A package shall contain no more than one Custom XML Mappings part, and that part shall be the target of an implicit relationship from the Workbook part (§12.3.23). The Worksheet part into which this data is imported shall also have a relationship file that targets one or more Table Definition (§12.3.21) parts and/or one or more Single Cell Table Defintions (§12.3.19) parts.

[*Example*: The following Workbook part-relationship item contains a relationship to the Custom XML Mappings part, which is stored in the ZIP item xmlMaps.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId9"
    Type="http://…/xmlMaps" Target="xmlMaps.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be mapInfo.

[*Example*: xmlMaps.xml contains the following:

```
<mapInfo SelectionNamespaces="">
  <Schema ID="Schema1">
    <xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
      <xsd:element nillable="true" name="names">
           <xsd:complexType>
          <xsd:sequence minOccurs="0">
            <xsd:element minOccurs="0" maxOccurs="unbounded"
              nillable="true" name="name" form="unqualified">
```

```
                    <xsd:complexType>
                      <xsd:sequence minOccurs="0">
                        <xsd:element minOccurs="0" nillable="true"
                          type="xsd:string" name="firstname"
                          form="unqualified"/>
                        <xsd:element minOccurs="0" nillable="true"
                          type="xsd:string" name="initial"
                          form="unqualified"/>
                        <xsd:element minOccurs="0" nillable="true"
                          type="xsd:string" name="lastName"
                          form="unqualified"/>
                      </xsd:sequence>
                    </xsd:complexType>
                  </xsd:element>
                </xsd:sequence>
              </xsd:complexType>
            </xsd:element>
          </xsd:schema>
        </Schema>
        <Map ID="1" Name="names_Map" RootElement="names" SchemaID="Schema1"
          ShowImportExportValidationErrors="false" AutoFit="true"
          Append="false"
          PreserveSortAFLayout="true" PreserveFormat="true">
          <DataBinding FileBinding="Test.xml" DataBindingLoadMode="1"/>
        </Map>
      </mapInfo>
```

end example]

A Custom XML Mappings part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Custom XML Mappings part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.7 Dialogsheet Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.dialogsheet+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/dialogsheet

An instance of this part type contains information about a legacy custom dialog box for a user form.

A package is permitted to contain one or more Dialogsheet parts, and each such part shall be the target of an explicit relationship from the Workbook part (§12.3.23).

[*Example*: The following Workbook part-relationship item contains relationships to a Dialogsheet part, which is stored in the ZIP item dialogsheets/sheet1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/dialogsheet" Target="dialogsheets/sheet1.xml"/>
</Relationships>
```

The Workbook part contains the following:

```
<workbook xmlns:r="…" …>
  …
  <sheets>
    …
    <sheet name="Dialog1" tabId="4" type="dialog" r:id="rId2"/>
  </sheets>
  …
</workbook>
```

end example]

The root element for a part of this content type shall be dialogsheet.

[*Example*: sheet1.xml contains the following:

```
<dialogsheet xmlns:r="…" …>
  <sheetPr>
    <pageSetUpPr/>
  </sheetPr>
  <sheetViews>
    …
  </sheetViews>
    …
  <legacyDrawing r:id="rId1"/>
</dialogsheet>
```

end example]

A Dialogsheet part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Dialogsheet part is permitted to have implicit relationships to the following parts defined by this Standard:

- Printer Settings (§15.2.14)

A Dialogsheet part is permitted to have explicit relationships to the following parts defined by this Standard:

- Embedded Control Persistence (§15.2.8)
- Drawings (§12.3.8)
- Embedded Object (§15.2.9)

A Dialogsheet part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.8 Drawings Part

Content Type:	application/vnd.openxmlformats-officedocument.drawing+xml
Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/spreadsheetDrawing
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/drawing

An instance of this part type contains the presentation and layout information for one or more drawing elements that are present on this worksheet.

A package is permitted to contain one or more Drawings parts, and each such part shall be the target of an explicit relationship from a Worksheet part (§12.3.24), or a Chartsheet part (§12.3.2). There shall be only one Drawings part per worksheet or chartsheet.

[*Example*: The following Chartsheet part-relationship item contains a relationship to a Drawings part, which is stored in the ZIP item ../drawings/drawing1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http:// …/drawing" Target="../drawings/drawing1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be wsDr.

[*Example*: drawing1.xml refers to a chart that is the target of a relationship in the Drawing part's relationship item:

```
<xdr:wsDr xmlns:xdr="…" xmlns:a="…">
  <xdr:absoluteAnchor>
    <xdr:pos x="1518046" y="-1443632"/>
    <xdr:extents cx="8587382" cy="5848945"/>
    <xdr:graphicFrame macro="">
      <xdr:nvGraphicFramePr>
        <xdr:cNvPr id="24" name="Chart 24" descr=""/>
        <xdr:cNvGraphicFramePr/>
      </xdr:nvGraphicFramePr>
      <xdr:xfrm>
        <a:off x="0" y="0"/>
        <a:ext cx="0" cy="0"/>
      </xdr:xfrm>
      <a:graphic>
        <a:graphicData uri="http://…/chart">
          <a:chart relId="rId1"/>
        </a:graphicData>
      </a:graphic>
    </xdr:graphicFrame>
    <xdr:clientData/>
  </xdr:absoluteAnchor>
</xdr:wsDr>
```

end example]

A Drawings part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Drawings part is permitted to have explicit relationships to the following parts defined by this Standard:

- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Hyperlinks (§15.3)
- Images (§15.2.13)

A Drawings part shall not have any implicit or explicit relationships to any other part defined by this Standard.

12.3.9 External Workbook References Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.externalLink+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/externalLink

An instance of this part specifies information about data referenced in other SpreadsheetML packages.

[*Example*: Consider two workbooks, wb1 and wb2, stored in packages called wb1.xlsx and wb2.xlsx, respectively. The value of a cell on a worksheet in wb1 can be computed using the value of one or more cells in wb2. This is done by having wb1 contain an external reference to wb2. *end example*]

A package is permitted to contain one or more External Workbook References parts, and those parts shall be the target of an explicit relationship in the Workbook part (§12.3.23).

[*Example*: A Workbook part for wb1 contains the following, which indicates that somewhere in its three worksheets, an external reference is made to a target specified in relationship id rId4 of the part's relationship item:

```
<workbook xmlns:r="…"/>
  …
  <sheets>
    <sheet name="Sheet1" tabId="1" r:id="rId1"/>
    <sheet name="Sheet2" tabId="2" r:id="rId2"/>
    <sheet name="Sheet3" tabId="3" r:id="rId3"/>
  </sheets>
  …
  <externalReferences>
    <externalReference r:id="rId4"/>
  </externalReferences>
  …
</workbook>
```

That part's relationship item contains the following:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/externalLink"
    Target="externalReferences/externalReference1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be externalLink.

[*Example*: externalReference1.xml contains:

```
<externalLink xmlns:r="…" … r:id="rId1">
  <externalBook>
    <sheetNames>
      <sheetName val="Sheet1"/>
      <sheetName val="Sheet2"/>
      <sheetName val="Sheet3"/>
    </sheetNames>
    <sheetDataSet>
      <sheetData sheetId="0">
        <row r="7">
          <cell r="C8">
            <v>0</v>
          </cell>
        </row>
      </sheetData>
      <sheetData sheetId="1"/>
      <sheetData sheetId="2"/>
    </sheetDataSet>
  </externalBook>
</externalLink>
```

This part's relationship item contains the following:

```
<Relationships …>
  <Relationship Id="rId1"
    Type="…/externalReference"
    Target="wb2.xlsx" TargetMode="External"/>
</Relationships>
```

where wb2.xlsx is the workbook in which one or more cells' values are used in calculating the values of a cell in workbook wb1. *end example*]

An External Workbook References part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

An External Workbook References part shall specify an explicit relationship to one or more this StandardExternal Workbooks (§12.4).

An External Workbook References part shall not have any implicit or explicit relationships to other parts defined by this Standard.

12.3.10 Metadata Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.sheetMetadata+xml

Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/sheetMetadata

An instance of this part type contains information relating to a cell whose value is related to one or more other cells via OnLine Analytical Processing (OLAP) technology.

A package shall contain no more than one Cell Metadata part, and that part shall be the target of an implicit relationship from the Workbook part (§12.3.23).

[*Example*: The following Workbook part-relationship item contains a relationship to the Metadata part, which is stored in the ZIP item metadata.xml. Cell B3 contains the formula `CUBEMEMBER ("externalData", "[Account].[All Account]")`:

```
<Relationships xmlns="…">
  <Relationship Id="rId10"
    Type="http://…/sheetMetadata" Target="metadata.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be `metadata`.

[*Example*: metadata.xml contains the following:

```
<metadata …>
  <metadataTypes count="1">
    <metadataType name="XLMDX" minSupportedVersion="120000" copy="1"
      pasteAll="1" pasteValues="1" merge="1" splitFirst="1" rowColShift="1"
      clearFormats="1" clearComments="1" assign="1" coerce="1"/>
  </metadataTypes>
  <metadataStrings count="2">
    <s v="externalData"/>
    <s v="[Account].[All Account]"/>
  </metadataStrings>
  <mdxMetadata count="1">
    <m n="0" f="m">
      <t c="1">
        <n v="1"/>
      </t>
    </m>
  </mdxMetadata>
```

```
    <valueMetadata count="1">
      <b>
        <r t="1" v="0"/>
      </b>
    </valueMetadata>
  </metadata>
```

The corresponding Connections part contains the following:

```
  <connections …>
    <connection id="1" odcFile="…" keepAlive="1" name="externalData"
      description="…" type="5" refreshedVersion="3" background="1">
      <dbPr connection="Provider=MSOLAP.2;…" command="Budget" commandType="1"/>
      <olapPr sendLocale="1" rowDrillCount="1000" serverFill="1"
        serverNumberFormat="1" serverFont="1" serverFontColor="1"/>
    </connection>
  </connections>
```

The corresponding Volatile Dependencies part contains the following:

```
  <volTypes …">
    <volType type="cubeFunctions">
      <main first="externalData">
        <tp t="e">
          <v>#N/A</v>
          <stp>1</stp>
          <r r="B3" s="1"/>
        </tp>
      </main>
    </volType>
  </volTypes>
```

The corresponding Pivot Table Cache Definition part contains the following:

```
  <pivotCacheDefinition … saveData="0" refreshedBy="…"
    refreshedDate="2005-11-28T16:55:44" backgroundQuery="1" createdVersion="3"
    refreshedVersion="3" recordCount="0">
    <cacheSource type="external" connectionID="1"/>
    <cacheFields count="0"/>
    <cacheHierarchies count="6">
      …
    </cacheHierarchies>
```

```
    <kpis count="0"/>
    <tupleCache>
      <queryCache count="3">
        <query mdx="[product].[category]"/>
        <query mdx=""/>
        <query mdx="[Account].[All Account]">
          <tpls c="1">
            <tpl hier="0" item="4294967295"/>
          </tpls>
        </query>
      </queryCache>
    </tupleCache>
  </pivotCacheDefinition>
```

end example]

A Metadata part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Metadata part shall not have implicit or explicit relationships to any part defined by this Standard.

12.3.11 Pivot Table Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.pivotTable+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/pivotTable

An instance of this part type contains a pivot table definition.

A package shall contain exactly one Pivot Table part per pivot table, and each such part shall be the target of an implicit relationship in the relationship part for the Worksheet part (§12.3.24) that corresponds to the worksheet containing the pivot table.

[*Example*: The following Worksheet part-relationship item contains a relationship to two Pivot Table parts, which are stored in the ZIP items ../pivotTables/pivotTable*N*.xml:

```
  <Relationships xmlns="…">
    <Relationship Id="rId1"
      Type="http://…/pivotTable" Target="../pivotTables/pivotTable1.xml"/>
    <Relationship Id="rId2"
      Type="http://…/pivotTable" Target="../pivotTables/pivotTable2.xml"/>
  </Relationships>
```

end example]

The root element for a part of this content type shall be pivotTableDefinition.

[*Example*: pivotTable1.xml contains the following:

```
<pivotTableDefinition … cache="4" applyNumberFormats="0" applyBorderFormats="0"
  applyFontFormats="0" applyPatternFormats="0" applyAlignmentFormats="0"
  applyWidthHeightFormats="1" dataCaption="Data" updatedVersion="3"
  minRefreshableVersion="3" useAutoFormatting="1" itemPrintTitles="1"
  createdVersion="3" indent="0" outline="1" outlineData="1">
  <location ref="H4:H5" firstHeaderRow="1" firstDataRow="1" firstDataCol="0"/>
  <pivotFields count="1">
    <pivotField dataField="1" numFmtId="0" outline="1"
      subtotalTop="1" showAll="0" measureFilter="0" sortType="manual"/>
  </pivotFields>
  <rowItems count="1">
    <i t="data"/>
  </rowItems>
  <colItems count="1">
    <i t="data"/>
  </colItems>
  <dataFields count="1">
    <dataField name="Sum of 1000" fld="0" subtotal="average"
      baseField="0" baseItem="0" numFmtId="0"/>
  </dataFields>
  <tableStyle name="TableStyle2" showRowHeaders="1" showColHeaders="1"
    showRowStripes="1" showColStripes="1"/>
</pivotTableDefinition>
```

end example]

A Pivot Table part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Pivot Table part is permitted to have implicit relationships to the following parts defined by this Standard:

- Pivot Table Cache Definition (§12.3.12).

A Pivot Table part shall not have any implicit or explicit relationships to other parts defined by this Standard.

12.3.12 Pivot Table Cache Definition Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.pivotCacheDefinition+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/pivotCacheDefinition

An instance of this part type contains a cache definition for a pivot table.

A package shall contain exactly one Pivot Table Cache Definition part per pivot table, and each such part shall be the target of an implicit relationship from a Pivot Table (§12.3.11) part as well as an explicit relationship from a Workbook (§12.3.23) part.

[*Example*: The following Pivot Table part-relationship item contains a relationship to the Pivot Table Cache Definition part, which is stored in the ZIP item ../pivotCache/pivotCacheDefinition2.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type=http://…/pivotCacheDefinition
    Target="../pivotCache/pivotCacheDefinition2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be pivotCacheDefinition.

[*Example*: pivotCacheDefinition2.xml contains the following:

```
<pivotCacheDefinition … r:id="rId1" refreshedBy="John Jones"
  refreshedDate="2005-11-18T16:47:49" createdVersion="3"
  refreshedVersion="3" recordCount="11">
  <cacheSource type="worksheet">
    <worksheet range="C4:C15" sheet="Sheet1"/>
  </cacheSource>
  <cacheFields count="1">
    <cacheField name="1000">
      <sharedItems containsSemiMixedTypes="0" containsString="0"
        containsNumber="1" containsInteger="1" minValue="234
        maxValue="2543"/>
    </cacheField>
  </cacheFields>
</pivotCacheDefinition>
```

end example]

A Pivot Table Cache Definition part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Pivot Table Cache Definition part is permitted to have an explicit relationship to the following part defined by this Standard:

- Pivot Table Cache Records (§12.3.13).

A Pivot Table Cache Definition part shall not have any implicit or explicit relationships to other parts defined by this Standard.

12.3.13 Pivot Table Cache Records Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.pivotCacheRecords+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/spreadsheetml/pivotCacheRecords

An instance of this part type contains the cache records for a pivot table.

A package shall contain exactly one Pivot Table Cache Records part per pivot table, and each such part shall be the target of an explicit relationship in the Pivot Table Cache Definition (§12.3.12) part for the corresponding pivot table.

[*Example*: The following Pivot Table Cache Definition part-relationship item contains a relationship to the Pivot Table Cache Records part, which is stored in the ZIP item pivotCacheRecords2.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/pivotCacheRecords" Target="pivotCacheRecords2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be pivotCacheRecords.

[*Example*: pivotCacheRecords2.xml contains the following:

```
<pivotCacheRecords … count="11">
  <r>
    <n v="1234"/>
  </r>
    …
  <r>
    <n v="876"/>
  </r>
</pivotCacheRecords>
```

end example]

A Pivot Table Cache Records part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Pivot Table Cache Records part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.14 Query Table Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.queryTable+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/queryTable

An instance of this part type contains information that describes how the source table is connected to an external data source, and defines the properties that is used when this table is refreshed from that source.

A package is permitted to contain one Query Table part per table, and each of those parts shall be the target of an implicit relationship from the corresponding Table Definitions (§12.3.21) part.

[*Example*: The following Table part-relationship item contains a relationship to the Query Table part corresponding to the connections details for that table. These parts are stored in the ZIP items ../queryTables/queryTable*n*.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/queryTable"
    Target="../queryTables/queryTable1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be queryTable.

[*Example*: queryTable2.xml deals with a connection to a database file having the seven fields shown:

```
<queryTable … name="+Connect to New Data Source_1"
  growShrinkType="insertDelete" connectionId="2" autoFormatId="16"
  applyNumberFormats="0" applyBorderFormats="0" applyFontFormats="1"
  applyPatternFormats="1" applyAlignmentFormats="0"
  applyWidthHeightFormats="0">
```

```
    <queryTableRefresh nextId="8">
      <queryTableFields count="7">
        <queryTableField id="1" name="ACCOUNT"/>
        <queryTableField id="2" name="CHECKNUM"/>
        <queryTableField id="3" name="DATE"/>
        <queryTableField id="4" name="AMOUNT"/>
        <queryTableField id="5" name="PAYEE"/>
        <queryTableField id="6" name="CHARGECODE"/>
        <queryTableField id="7" name="DESCRIPT"/>
      </queryTableFields>
    </queryTableRefresh>
  </queryTable>
```

end example]

A Query Table part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Query Table part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.15 Shared String Table Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.sharedStrings+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/sharedStrings

An instance of this part type contains one occurrence of each unique string that occurs on all worksheets in a workbook.

A package shall contain exactly one Shared String Table part, and that part shall be the target of an implicit relationship from the Workbook part (§12.3.23).

[*Example*: The following Workbook part-relationship item contains a relationship to the Shared String Table part, which is stored in the ZIP item sharedStrings.xml:

```
  <Relationships xmlns="…">
    <Relationship Id="rId6"
      Type="http://…/sharedStrings" Target="sharedStrings.xml"/>
  </Relationships>
```

end example]

The root element for a part of this content type shall be sst.

[*Example*: Here are three of the six strings used in the worksheets:

```
<sst xmlns:st="…" … totalCount="6" uniqueCount="6">
  <sstItem>
    <t>Expenses Log</t>
  </sstItem>
  <sstItem>
    <t>Period Start</t>
  </sstItem>
  <sstItem>
    <t>Period End</t>
  </sstItem>
  …
</sst>
```

end example]

A Shared String Table part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Shared String Table part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.16 Shared Workbook Revision Headers Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.revisionHeaders+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/revisionHeaders

An instance of this part type contains information about each of the editing sessions performed on the parent workbook at the worksheet level (worksheets added and rearranged in each session).

A package shall contain at most one Shared Workbook Revision Headers part. If it exists, that part shall be the target of an implicit relationship from the Workbook (§12.3.23) part.

[*Example*: The following Workbook part-relationship item contains a relationship to the Shared Workbook Revision Headers part, which is stored in the ZIP item handout revisions/revisionHeaders.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId9"
    Type="http://…/revisionHeaders"
    Target="revisions/revisionHeaders.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be headers.

[*Example*: revisionHeaders.xml contains the following:

```
<headers xmlns:r="…" guid="{233BEE23-EB5C-4542-905D-0230EFFED88B}"
  diskRevisions="1" revisionId="4" version="3">
  <header guid="…" dateTime="…" maxSheetId="4" userName="…" r:id="rId1">
    <sheetIdMap count="3">
      …
    </sheetIdMap>
  </header>
  …
  <header guid="…" dateTime="…" maxSheetId="4" userName="…" r:id="rId3">
    <sheetIdMap count="3">
      …
    </sheetIdMap>
  </header>
</headers>
```

end example]

A Shared Workbook Revision Headers part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Shared Workbook Revision Headers part is permitted to have explicit relationships to the following parts defined by this Standard:

- Shared Workbook Revision Log (§12.3.17)

A Shared Workbook Revision Headers part shall not have any implicit or explicit relationships to other parts defined by this Standard.

12.3.17 Shared Workbook Revision Log Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.revisionLog+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/revisionLog

An instance of this part type contains information about edits performed on individual cells in the parent workbook's worksheets in each editing session.

A package shall contain one Shared Workbook Revision Log part for each session's set of changes, and those parts shall be the target of an explicit relationship from the Shared Workbook Revision Headers (§12.3.16) part.

[*Example*: The following Shared Workbook Revision Headers part-relationship item contains a number of relationships to Shared Workbook Revision Log parts, which are stored in the ZIP item revisionLog*N*.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/revisionLog" Target="revisionLog1.xml"/>
  …
  <Relationship Id="rId6"
    Type="http://…/revisionLog" Target="revisionLog6.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be revisions.

[*Example*: revisionLog2.xml contains the following:

```
<revisions xmlns:xs="…" …>
  <rfmt sheetId="1" sqref="B4:B15">
    <dxf>
      <xs:fill>
        <xs:pattern patternType="solid">
          <xs:fgColor type="icv" val="64"/>
          <xs:bgColor type="rgb" val="4278252287"/>
        </xs:pattern>
      </xs:fill>
    </dxf>
  </rfmt>
  <rcv guid="{CBCE5672-5A4D-48C9-A120-F72804F8CF64}" action="delete"/>
  <rcv guid="{CBCE5672-5A4D-48C9-A120-F72804F8CF64}" action="add"/>
</revisions>
```

end example]

A Shared Workbook Revision Log part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Shared Workbook Revision Log part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.18 Shared Workbook User Data Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.userNames+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/usernames

An instance of this part type contains a list of all the users that are sharing the parent workbook.

A package shall contain at most one Shared Workbook User Data part, and that part shall be the target of an implicit relationship in the Workbook (§12.3.23) part.

[*Example*: The following Workbook part-relationship item contains a relationship to the Shared Workbook User Data part, which is stored in the ZIP item revisions/userNames.xml:

```
<Relationships xmlns="…">
  Relationship Id="rId8"
    Type="http://…/usernames" Target="revisions/userNames.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be users.

[*Example*: userNames.xml shows that there are two users sharing this workbook:

```
<users … count="2">
  <usrinfo guid="{B5A024F7-40BE-4A48-9B6D-B1655241C84D}"
    name="Mary Jones" id="-264292310" dateTime="2005-11-18T18:53:16"/>
  <usrinfo …/>
</users>
```

end example]

A Shared Workbook User Data part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Shared Workbook User Data part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.19 Single Cell Table Definitions Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.tableSingleCells+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/tableSingleCells

An instance of this part type contains information on how to map non-repeating elements from a custom XML file into cells in a worksheet. [*Note*: Repeating custom XML elements are mapped using a Table (§12.3.21). *end note*]

A package shall contain at most one Single Cell Table Definitions part per worksheet, and that part shall be the target of an implicit relationship from a Worksheet (§12.3.24) part. A Single Cell Table Definitions part can describe one or more single cell table definitions for any given worksheet.

[*Example*: The following Worksheet part-relationship item contains a relationship to the Single Cell Table Definitions part, which is stored in the ZIP item ../tables/tableSingleCells1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/tableSingleCells"
    Target="../tables/tableSingleCells1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be singleCells.

[*Example*: A worksheet contains two single cell table definitions; e.g., ../tables/tableSingleCells1.xml contains the following, where the elements id and count are nested inside element names:

```
<singleCells …>
  <singleCell id="1" name="Table1" displayName="Table1" ref="B4">
    <cellPr id="1" uniqueName="id">
      <xmlPr mapId="1" xpath="/names/id" xmlDataType="string"/>
    </cellPr>
  </singleCell>
  <singleCell id="2" name="Table2" displayName="Table2" ref="B7">
    <cellPr id="1" uniqueName="count">
      <xmlPr mapId="1" xpath="/names/count" xmlDataType="integer"/>
    </cellPr>
  </singleCell>
</singleCells>
```

end example]

A Single Cell Table Definitions part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Single Cell Table Definitions part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.20 Styles Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.styles+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/mains
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/styles

An instance of this part type contains all the characteristics for all the cells in the workbook. Such information includes numeric and text formatting, alignment, font, color, and border.

A package shall contain no more than one Styles part, and that part shall be the target of an implicit relationship from the Workbook (§12.3.23) part.

[*Example*: The following Workbook part-relationship item contains a relationship to the Styles part, which is stored in the ZIP item styles.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId5"
    Type="http://…/styles" Target="styles.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be styleSheet.

[*Example*:

```
<styleSheet xmlns="…">
  <numFmts count="5">
    <numFmt numFmtId="164" formatCode="&quot;$&quot;#,##0.00"/>
    <numFmt numFmtId="165"
      formatCode="&quot;Yes&quot;;&quot;Yes&quot;;&quot;No&quot;"/>
    <numFmt numFmtId="166"
      formatCode="&quot;True&quot;;&quot;True&quot;;&quot;False&quot;"/>
    <numFmt numFmtId="167"
      formatCode="&quot;On&quot;;&quot;On&quot;;&quot;Off&quot;"/>
    <numFmt numFmtId="168"
      formatCode="[$€-2]\ #,##0.00_);[Red]\([$€-2]\ #,##0.00\)"/>
  </numFmts>
```

```
    <fonts count="5">
      …
    </fonts>
    <fills count="4">
      …
    </fills>
    <borders count="1">
      …
    </borders>
    …
    <colors>
      …
    </colors>
  </styleSheet>
```

end example]

A Styles part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Styles part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.21 Table Definition Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.table+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/table

An instance of this part type contains a description of a single table and its autofilter information. (The data for the table is stored in the corresponding Worksheet part.)

A package shall contain one Table Definition part per table, and each such part shall be the target of an implicit relationship from the Worksheet (§12.3.24) part that corresponds to the worksheet containing that table.

[*Example*: The following Worksheet part-relationship item contains relationships to two Table Definition parts, which are stored in the ZIP items ../tables/table*N*.xml:

```
  <Relationships xmlns="…">
    <Relationship Id="rId2"
      Type="http://…/table" Target="../tables/table1.xml"/>
    <Relationship Id="rId3"
      Type="http://…/table" Target="../tables/table2.xml"/>
  </Relationships>
```

end example]

The root element for a part of this content type shall be table.

[*Example*: table2.xml describes a table that spans a 2-column range of cells, F2:G19:

```
<table xmlns:af="…" … id="2" name="Table2" displayName="Table2" ref="F2:G19"
  totalsRowShown="0" headerRowDxfId="7">
  <autoFilter ref="F2:G19"/>
  <tableColumns count="2">
    <tableColumn id="1" name="Salesman" dataDxfId="9" totalsRowDxfId="6"/>
    <tableColumn id="2" name="Units" dataDxfId="8" totalsRowDxfId="5"/>
  </tableColumns>
  <tableStyle name="TableStyle2" showFirstColumn="0" showLastColumn="0"
    showRowStripes="1" showColumnStripes="1"/>
</table>
```

When the filter "Salesman equal to Smith" is applied, the autoFilter element in table2.xml is extended, as follows:

```
<autoFilter ref="F2:G19">
  <af:filterColumn colId="0">
    <af:filters>
      <af:filter val="Smith"/>
    </af:filters>
  </af:filterColumn>
</autoFilter>
```

end example]

A Table Definition part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be Internal).

A Table Definition part is permitted to explicit relationships to the following parts defined by this Standard:

- Query Table (§12.3.14)

A Table Definition part shall not have any implicit or explicit relationships to any other part defined by this Standard.

12.3.22 Volatile Dependencies Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.volatileDependencies+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/volatileDependencies

An instance of this part type contains information involving real-time data formulas in a workbook.

A package shall contain exactly one Volatile Dependencies part, and that part shall be the target of an implicit relationship from the Workbook (§12.3.23) part.

[*Example*: The following Workbook part-relationship item contains a relationship to the Volatile Dependencies part, which is stored in the ZIP item volatileDependencies.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId8"
    Type="http://…/volatileDependencies"
    Target="volatileDependencies.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be volTypes.

[*Example*:

```
<volTypes xmlns="…"/>
```

end example]

A Volatile Dependencies part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Volatile Dependencies part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.23 Workbook Part

Content Type(s):	application/vnd.openxmlformats-officedocument.spreadsheetml.main+xml application/vnd.openxmlformats-officedocument.spreadsheetml.template.main+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/officeDocument

An instance of this part type contains workbook data and references to all of its worksheets.

A package shall contain exactly one Workbook part, and that part shall be the target of a relationship in the package-relationship item.

[*Example*: The following SpreadsheetML package-relationship item contains a relationship to the Workbook part, which is stored in the ZIP item xl/workbook.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/officeDocument" Target="xl/workbook.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be workbook.

[*Example*: This workbook has three worksheets, named January, February, and March:

```
<workbook xmlns="…" xmlns:r="…">
  <fileVersion lastEdited="4" lowestEdited="4" rupBuild="3417"/>
  <bookViews>
    <workbookView xWindow="240" yWindow="15" windowWidth="8505"
      windowHeight="6240"/>
  </bookViews>
  <sheets>
    <sheet name="January" tabId="1" r:id="rId1"/>
    <sheet name="February" tabId="2" r:id="rId2"/>
    <sheet name="March" tabId="3" r:id="rId3"/>
  </sheets>
  <workbookPr showObjects="all"/>
  <webPublishing codePage="1252"/>
  <calcPr calcId="122211" fullCalcOnLoad="1"/>
</workbook>
```

end example]

A Workbook part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Workbook part is permitted to have implicit relationships to the following parts defined by this Standard:

- Additional Characteristics (§15.2.1)
- Bibliography (§15.2.3)
- Calculation Chain (§12.3.1)
- Cell Metadata (§12.3.10)
- Connections (§12.3.4)
- Custom XML Mappings (§12.3.6)

- Custom XML Data Storage (§15.2.4)
- Shared String Table (§12.3.15)
- Shared Workbook Revision Headers (§12.3.16)
- Shared Workbook User Data (§12.3.18)
- Styles (§12.3.20)
- Theme (§14.2.7)
- Thumbnail (§15.2.14)
- Volatile Dependencies (§12.3.22)

A Workbook part is permitted to have explicit relationships to the following parts defined by this Standard:

- Chartsheet (§12.3.2)
- Dialogsheet (§12.3.7)
- External Workbook References (§12.3.8)
- Pivot Table Cache Definition (§12.3.12)
- Worksheet (§12.3.24)

A Workbook part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.3.24 Worksheet Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.worksheet+xml
Root Namespace:	http://schemas.openxmlformats.org/spreadsheetml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/worksheet

An instance of this part type contains all the data, formulas, and characteristics associated with a given worksheet.

A package shall contain exactly one Worksheet part per worksheet, and those parts shall be the target of an explicit relationship from the Workbook (§12.3.23) part. Specifically, the id attribute on the sheet element shall reference the desired worksheet part.

[*Example*: The following Workbook part-relationship item contains three relationships to Worksheet parts, which are stored in the ZIP items worksheets/sheet*N*.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/worksheet" Target="worksheets/sheet1.xml"/>
  <Relationship Id="rId2"
    Type="http://…/worksheet" Target="worksheets/sheet2.xml"/>
  <Relationship Id="rId3"
    Type="http://…/worksheet" Target="worksheets/sheet3.xml"/>
 </Relationships>
```

end example]

The root element for a part of this content type shall be worksheet.

[*Example*: This worksheet, has cells in the range B1 to F8. Row 8 contains three cells whose values are calculated using the following formulas: D8=SUM(D5:D7), E8=SUM(E5:E7), and F8= D8-E8:

```
<worksheet xmlns="…" …>
  <sheetPr/>
  <dimension range="B1:F8"/>
  …
  <sheetData>
    <row r="1" spans="2:6" ht="360">
      <c r="B1" s="1" t="s">
        <v>0</v>
      </c>
    </row>
    …
    <row r="8" spans="2:6" ht="360">
      <c r="D8" s="5">
        <f>SUM(D5:D7)</f>
        <v>2280.5299999999997</v>
      </c>
      <c r="E8" s="5">
        <f>SUM(E5:E7)</f>
        <v>1251.31</v>
      </c>
      <c r="F8" s="6">
        <f>D8-E8</f>
        <v>1029.2199999999998</v>
      </c>
    </row>
  </sheetData>
  …
</worksheet>
```

end example]

A Worksheet part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Worksheet part is permitted to contain implicit relationships to the following parts defined by this Standard:

- Comments (§12.3.3)
- Pivot Table Definitions (§12.3.11)
- Printer Settings (§15.2.14)
- Single Cell Table Definitions (§12.3.19)
- Table Definition (§12.3.21)

A Worksheet part is permitted to contain explicit relationships to the following parts defined by this Standard:

- Drawings (§12.3.8)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlinks (§15.3)
- Images (§15.2.13)
- VML Drawing (§15.2.17)

A Worksheet part shall not have implicit or explicit relationships to any other part defined by this Standard.

12.4 External Workbooks

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/externalLinkPath

An *external workbook* is a SpreadsheetML package whose contents are being referenced by the current SpreadsheetML package. When a package refers to external workbooks, it shall store the location of those workbooks using this relationship.

A package is permitted to contain one or more External Workbook relationships, and those relationships shall be an explicit relationship from the External Workbook References (§12.3.9) part.

[*Example*: An External Workbook References part, which references the package c:\sourceData.xlsx would have an External Workbook relationship, which points at that file:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/externalLinkPath"
    Target="c:\sourceData.xlsx" TargetMode="External"/>
</Relationships>
```

end example]

A external workbook shall be located external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `External`).

13. PresentationML

This clause contains specifications for relationship items and parts that are specific to PresentationML. Parts than can occur in a PresentationML document, but are not PresentationML-specific, are specified in §15.2. Unless stated explicitly, all references to relationship items, content-type items, and parts in this clause refer to PresentationML ZIP items.

13.1 Glossary of PresentationML-Specific Terms

The following terms are used in the context of a PresentationML document:

comment — A note that an author or reviewer attaches to a piece of text in a document. Although a consumer may chose to display comments, they are not considered part of the body of the document. A comment includes the text of the note, the comment author's name and initials, and date of creation, among other things.

handout — A printed set of slides that can be handed out to an audience for future reference.

note — A slide annotation, reminder, or piece of text intended for the presenter or the audience.

presentation — A collection of slides intended to be viewed by an audience.

slide — A frame containing one or more pieces of text and/or images.

slide layout — The organization of elements on a slide.

13.2 Package Structure

A PresentationML package shall contain a package-relationship item and a content-type item. The package-relationship item shall contain implicit relationships with targets of the following type:

- One Presentation part (§13.3.6).

The package-relationship item is permitted to contain implicit relationships with targets of the following type:

- Digital Signature Origin (§15.2.6)
- File Property parts (§15.2.11) (Application-Defined File Properties, Core File Properties, and Custom File Properties), as appropriate.
- Thumbnail (§15.2.14).

The required and optional relationships between parts are defined in §13.3 and its subordinate clauses.

[*Example*: The following package represents the minimal conformant PresentationML package as defined by this Standard:

First, the content type for relationship parts and the Main Presentation part (the only required part) must be defined (physically located at /[Content_Types].xml in the package):

```
<Types xmlns="…">
  <Default Extension="rels"
    ContentType="application/vnd.openxmlformats-
      package.relationships+xml"/>
  <Override PartName="/presentation.xml"
    ContentType="application/vnd.openxmlformats-
      officedocument.presentationml.presentation.main+xml"/>
</Types>
```

Next, the single required relationship (the package-level relationship to the Main Presentation part) must be defined (physically located at /_rels/.rels in the package):

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://schemas.openxmlformats.org/officeDocument/2006/
      relationships/officeDocument"
    Target="presentation.xml"/>
</Relationships>
```

Finally, the minimum content for the Main Presentation part must be defined (physically located at /presentation.xml in the package):

```
<p:presentation xmlns:p="…">
  <p:notesSz cx="913607" cy="913607"/>
</p:presentation>
```

end example]

[*Example*: Consider a simple PresentationML document containing two slides, which both use an image as a template. Here's an example of the hierarchical folder structure that might be used for the ZIP items in the package for that document. As shown, a number of parts have their own relationship items:

```
/_rels/.rels                          Package-relationship item
/[Content_Types].xml                  Content-type item
/docProps/app.xml                     Application-Defined File
Properties part
/docProps/core.xml                    Core File Properties part
/docProps/custom.xml                  Custom File Properties part
/docProps/thumbnail.wmf               Package thumbnail image
/ppt/presentation.xml                 Presentation part
/ppt/_rels/presentation.xml.rels      Part-relationship item
```

```
/ppt/presProps.xml                              Presentation Properties part
/ppt/tableStyles.xml                            Table Styles part
/ppt/viewProps.xml                              View Properties part
/ppt/handoutMasters/handoutMaster1.xml          Handout Master part
/ppt/handoutMasters/_rels/handoutMaster1.xml.rels
                                                Part-relationship item
/ppt/media/image1.jpeg                          Slide template image
/ppt/notesMasters/notesMaster1.xml              Notes Master part
/ppt/notesMasters/_rels/notesMaster1.xml.rels
                                                Part-relationship item
/ppt/notesSlides/notesSlide1.xml                Notes Slide parts
/ppt/notesSlides/notesSlide2.xml
/ppt/notesSlides/_rels/notesSlide1.xml.rels
                                                Part-relationship items
/ppt/notesSlides/_rels/notesSlide2.xml.rels
/ppt/slideLayouts/slideLayout1.xml              Slide Layout parts 1–6
/ppt/slideLayouts/slideLayout2.xml
/ppt/slideLayouts/slideLayout3.xml
/ppt/slideLayouts/slideLayout4.xml
/ppt/slideLayouts/slideLayout5.xml
/ppt/slideLayouts/slideLayout6.xml
/ppt/slideLayouts/_rels/slideLayout1.xml.rels
                                                Part-relationship items
/ppt/slideLayouts/_rels/slideLayout2.xml.rels
/ppt/slideLayouts/_rels/slideLayout3.xml.rels
/ppt/slideLayouts/_rels/slideLayout4.xml.rels
/ppt/slideLayouts/_rels/slideLayout5.xml.rels
/ppt/slideLayouts/_rels/slideLayout6.xml.rels
/ppt/slideMasters/slideMaster1.xml              Slide Master part
/ppt/slideMasters/_rels/slideMaster1.xml.rels
                                                Part-relationship item
/ppt/slides/slide1.xml                          Slide parts
/ppt/slides/slide2.xml
/ppt/slides/_rels/slide1.xml.rels               Part-relationship items
/ppt/slides/_rels/slide2.xml.rels
/ppt/theme/theme1.xml                           Theme parts
/ppt/theme/theme2.xml
/ppt/theme/theme3.xml
```

```
/ppt/theme/themeOverride1.xml                    Theme Override parts
/ppt/theme/themeOverride2.xml
/ppt/theme/themeOverride3.xml
/ppt/theme/themeOverride4.xml
/ppt/theme/themeOverride5.xml
/ppt/theme/themeOverride6.xml
/ppt/theme/themeOverride7.xml
/ppt/theme/themeOverride8.xml
/ppt/theme/themeOverride9.xml
/ppt/theme/themeOverride10.xml
```

The package-relationship item contains the following:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/officeDocument" Target="ppt/presentation.xml"/>
  <Relationship Id="rId3"
    Type="http://…/core-properties" Target="docProps/core.xml"/>
  <Relationship Id="rId2"
    Type="http://…/thumbnail" Target="docProps/thumbnail.wmf"/>
  <Relationship Id="rId4"
    Type="http://…/extended-properties" Target="docProps/app.xml"/>
</Relationships>
```

end example]

13.3 Part Summary

The subclauses subordinate to this one describe in detail each of the part types specific to PresentationML.

[*Note*: For convenience, information from those subclauses is summarized in the following table:

Part	Relationship Target of	Root Element	Ref.
Comment Authors	Presentation	cmAuthorLst	§13.3.1
Comments	Slide	cmLst	§13.3.2
Handout Master	Presentation	handoutMaster	§13.3.3
Notes Master	Notes Slide, Presentation	notesMaster	§13.3.4
Notes Slide	Slide	notes	§13.3.5
Presentation	PresentationML package	presentation	§13.3.6
Presentation Properties	Presentation	presentationPr	§13.3.7
Slide	Presentation	sld	§13.3.8

Part	Relationship Target of	Root Element	Ref.
Slide Layout	Slide Master, Notes Slide, Presentation, Slide, Slide Master	sldLayout	§13.3.9
Slide Master	Presentation, Slide Layout	sldMaster	§13.3.10
Slide Synchronization Data	Slide	sldSyncPr	§13.3.11
User-Defined Tags	Presentation, Slide	tagLst	§13.3.12
View Properties	Presentation	viewPr	§13.3.13

end note]

13.3.1 Comment Authors Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.commentAuthors+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/commentAuthors

An instance of this part type contains information about each author who has added a comment to the document. That information includes the author's name, initials, a unique author-ID, a last-comment-index-used count, and a display color. (The color can be used when displaying comments to distinguish comments from different authors.)

A package shall contain at most one Comment Authors part. If it exists, that part shall be the target of an implicit relationship from the Presentation (§13.3.6) part.

[*Example*: The following Presentation part relationship item contains a relationship to the Comment Authors part, which is stored in the ZIP item commentAuthors.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId8"
    Type="http://…/commentAuthors" Target="commentAuthors.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be cmAuthorLst.

[*Example*: Two people have authored comments in this document: Mary Smith and Peter Jones. Her initials are "mas", her author-ID is 0, and her comments' display color index is 0. Since Mary's last-comment-index-used value is 3, the next comment-index to be used for her will be 4. His initials are "pjj", his author-ID is 1, and his

comments' display color index is 1. Since Peter's last-comment-index-used value is 1, the next comment-index to be used for him will be 2:

```
<p:cmAuthorLst xmlns:p="…" …>
  <p:cmAuthor id="0" name="Mary Smith" initials="mas" lastIdx="3"
    clrIdx="0"/>
  <p:cmAuthor id="1" name="Peter Jones" initials="pjj" lastIdx="1"
    clrIdx="1"/>
</p:cmAuthorLst>
```

end example]

A Comment Authors part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Comment Authors part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.2 Comments Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.comments+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/comments

An instance of this part type contains the comments for a single slide. Each comment is tied to its author via an author-ID. Each comment's index number and author-ID combination are unique.

A package shall contain one Comments part for each slide containing one or more comments, and each of those parts shall be the target of an implicit relationship from its corresponding Slide (§13.3.8) part.

[*Example*: The following Slide part-relationship item contains a relationship to a Comments part, which is stored in the ZIP item ../comments/comment2.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/comments"
    Target="../comments/comment2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be cmLst .

[*Example*: The Comments part contains three comments, two created by one author, and one created by another, all at the dates and times shown. The index numbers are assigned on a per-author basis, starting at 1 for an author's first comment:

```
<p:cmLst xmlns:p="…" …>
  <p:cm authorId="0" dt="2005-11-13T17:00:22.071" idx="1">
    <p:pos x="4486" y="1342"/>
    <p:text>Comment text goes here.</p:text>
  </p:cm>
  <p:cm authorId="0" dt="2005-11-13T17:00:34.849" idx="2">
    <p:pos x="3607" y="1867"/>
    <p:text>Another comment's text goes here.</p:text>
  </p:cm>
  <p:cm authorId="1" dt="2005-11-15T00:06:46.919" idx="1">
    <p:pos x="1493" y="2927"/>
    <p:text>comment …</p:text>
  </p:cm>
</p:cmLst>
```

end example]

A Comments part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Comments part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.3 Handout Master Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.handoutMaster+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/handoutMaster

An instance of this part type contains the look, position, and size of the slides, notes, header and footer text, date, or page number on the presentation's handout.

A package shall contain at most one Handout Master part, and it shall be the target of an explicit relationship from the Presentation (§13.3.6) part.

[*Example*: The following Presentation part-relationship item contains a relationship to the Handout Master part, which is stored in the ZIP item handoutMasters/handoutMaster1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId5"
    Type="http://…/handoutMaster"
    Target="handoutMasters/handoutMaster1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be handoutMaster.

[*Example*:

```
<p:handoutMaster xmlns:p="…">
  <p:cSld name="">
    …
  </p:cSld>
  <p:clrMap … />
</p:handoutMaster>
```

end example]

A Handout Master part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Handout Master part is permitted to have implicit relationships to the following parts defined by this Standard:

- Additional Characteristics (§15.2.1)
- Bibliography (§15.2.3)
- Custom XML Data Storage (§15.2.4)
- Theme (§14.2.7)
- Thumbnail (§15.2.14)

A Handout Master part is permitted to have explicit relationships to the following parts defined by this Standard:

- Audio (§15.2.2)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlink (§15.3)
- Image (§15.2.13)

- Video (§15.2.14)
- VML Drawing (§15.2.17)

A Handout Master part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.4 Notes Master Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.notesMaster+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/notesMaster

An instance of this part type contains information about the content and formatting of all notes pages.

A package shall contain at most one Notes Master part, and that part shall be the target of an implicit relationship from the Notes Slide (§13.3.5) part, as well as an explicit relationship from the Presentation (§13.3.6) part.

[*Example*: The following Presentation part-relationship item contains a relationship to the Notes Master part, which is stored in the ZIP item notesMasters/notesMaster1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/notesMaster" Target="notesMasters/notesMaster1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be notesMaster.

[*Example*:

```
<p:notesMaster xmlns:p="…">
  <p:cSld name="">
    …
  </p:cSld>
  <p:clrMap … />
</p:notesMaster>
```

end example]

A Notes Master part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Notes Master part is permitted to have implicit relationships to the following parts defined by this Standard:

- Additional Characteristics (§15.2.1)
- Bibliography (§15.2.3)
- Custom XML Data Storage (§15.2.4)
- Theme (§14.2.7)
- Thumbnail (§15.2.14)

A Notes Master part is permitted to have explicit relationships to the following parts defined by this Standard:

- Audio (§15.2.2)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlink (§15.3).
- Image (§15.2.13)
- Video (§15.2.14)
- VML Drawing (§15.2.17)

The Notes Master part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.5 Notes Slide Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.notesSlide+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/notesSlide

An instance of this part type contains the notes for a single slide.

A package shall contain one Notes Slide part for each slide that contains notes. If they exist, those parts shall each be the target of an implicit relationship from the Slide (§13.3.8) part.

[*Example*: The following Slide part-relationship item contains a relationship to a Notes Slide part, which is stored in the ZIP item ../notesSlides/notesSlide1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId3"
    Type="http://…/notesSlide" Target="../notesSlides/notesSlide1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be notes.

[*Example*:

```
<p:notes xmlns:p="…">
  <p:cSld name="">
    …
  </p:cSld>
  <p:clrMapOvr>
    <a:masterClrMapping/>
  </p:clrMapOvr>
</p:notes>
```

end example]

A Notes Slide part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Notes Slide part is permitted to have implicit relationships to the following parts defined by this Standard:

- Additional Characteristics (§15.2.1)
- Bibliography (§15.2.3)
- Custom XML Data Storage (§15.2.4)
- Notes Master (§13.3.4)
- Theme Override(§14.2.8)
- Thumbnail (§15.2.14)

A Notes Slide part is permitted to have explicit relationships to the following parts defined by this Standard:

- Audio (§15.2.2)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlink (§15.3).
- Image (§15.2.13)

- Video (§15.2.14)
- VML Drawing (§15.2.17)

The Notes Slide part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.6 Presentation Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.presentation.main+xml application/vnd.openxmlformats-officedocument.presentationml.slideshow.main+xml application/vnd.openxmlformats-officedocument.presentationml.template.main+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/officeDocument

An instance of this part type contains the definition for a slide presentation.

A package shall contain exactly one Presentation part, and that part shall be the target of a relationship in the package-relationship item.

[*Example*: The following PresentationML's package-relationship item contains a relationship to the Presentation part, which is stored in the ZIP item ppt/presentation.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/officeDocument" Target="ppt/presentation.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be presentation.

[*Example*: This presentation contains two slides:

```
<p:presentation xmlns:p="…" … >
  <p:sldMasterIdLst>
    <p:sldMasterId
      xmlns:rel="http://…/relationships" rel:id="rId1"/>
  </p:sldMasterIdLst>
  <p:notesMasterIdLst>
    <p:notesMasterId
      xmlns:rel="http://…/relationships" rel:id="rId4"/>
  </p:notesMasterIdLst>
```

```
    <p:handoutMasterIdLst>
      <p:handoutMasterId
         xmlns:rel="http://…/relationships" rel:id="rId5"/>
    </p:handoutMasterIdLst>
    <p:sldIdLst>
      <p:sldId id="267"
        xmlns:rel="http://…/relationships" rel:id="rId2"/>
      <p:sldId id="256"
        xmlns:rel="http://…/relationships" rel:id="rId3"/>
    </p:sldIdLst>
    <p:sldSz cx="9144000" cy="6858000"/>
    <p:notesSz cx="6858000" cy="9144000"/>
  </p:presentation>
```

end example]

A Presentation part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Presentation part is permitted to have implicit relationships to the following parts defined by this Standard:

- Additional Characteristics (§15.2.1)
- Comments (§13.3.2)
- Bibliography (§15.2.3)
- Custom XML Data Storage (§15.2.4)
- Font (§15.2.12)
- Presentation Properties (§13.3.7)
- Table Styles (§14.2.9)
- Theme (§14.2.7)
- Thumbnail (§15.2.14)
- View Properties (§13.3.13).

A Presentation part is permitted to have explicit relationships to the following parts defined by this Standard:

- Notes Master (§13.3.4)
- Handout Master (§13.3.3)
- Slide (§13.3.8)
- Slide Layout (§13.3.9)
- Slide Master (§13.3.10)
- User Defined Tags (§13.3.12)

13.3.7 Presentation Properties Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.presentationProperties+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/presProps

An instance of this part type contains all the presentation's properties.

A package shall contain exactly one Presentation Properties part, and that part shall be the target of an implicit relationship from the Presentation (§13.3.6) part.

[*Example*: The following Presentation part-relationship item contains a relationship to the Presentation Properties part, which is stored in the ZIP item presProps.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId6"
    Type="http://…/presProps" Target="presProps.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be presentationPr.

[*Example*:

```
<p:presentationPr xmlns:p="…" …>
  <p:clrMru>
    …
  </p:clrMru>
  …
</p:presentationPr>
```

end example]

A Presentation Properties part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Presentation Properties part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.8 Slide Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.slide+xml

Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/slide

A Slide part contains the contents of a single slide.

A package shall contain one Slide part per slide, and each of those parts shall be the target of an explicit relationship from the Presentation (§13.3.6) part.

[*Example*: Consider a PresentationML document having two slides. The corresponding Presentation part-relationship item contains two relationships to Slide parts, which are stored in the ZIP items slides/slide1.xml and slides/slide2.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/slide" Target="slides/slide1.xml"/>
  <Relationship Id="rId3"
    Type="http://…/slide" Target="slides/slide2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be sld.

[*Example*: slides/slide1.xml contains:

```
<p:sld xmlns:p="…">
  <p:cSld name="">
    …
  </p:cSld>
  <p:clrMapOvr>
    …
  </p:clrMapOvr>
  <p:timing>
    <p:tnLst>
      <p:par>
        <p:cTn id="1" dur="indefinite" restart="never" nodeType="tmRoot"/>
      </p:par>
    </p:tnLst>
  </p:timing>
</p:sld>
```

end example]

A Slide part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Slide part is permitted to have implicit relationships to the following parts defined by this Standard:

- Additional Characteristics (§15.2.1)
- Bibliography (§15.2.3)
- Comments (§12.3.3)
- Custom XML Data Storage (§15.2.4)
- Notes Slide (§13.3.5)
- Theme Override (§14.2.8)
- Thumbnail (§15.2.14)
- Slide Layout (§13.3.9)
- Slide Synchronization Data (§13.3.11)

A Slide part is permitted to have explicit relationships to the following parts defined by this Standard:

- Audio (§15.2.2)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlink (§15.3).
- Image (§15.2.13)
- User Defined Tags (§13.3.12)
- Video (§15.2.14)
- VML Drawing (§15.2.17)

A Slide part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.9 Slide Layout Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.slideLayout+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/slideLayout

An instance of this part type contains the definition for a slide layout template for this presentation. This template defines the default appearance and positioning of drawing objects on this slide type when it is created.

A package shall contain one or more Slide Layout parts, and those parts shall be the target of an explicit relationship in the Presentation (§13.3.6) part, as well as an implicit relationship from the Slide Master (§13.3.10) part associated with this slide layout.

[*Example*: The following Slide Master part-relationship item contains relationships to several Slide Layout parts, which are stored in the ZIP items ../slideLayouts/slideLayout*N*.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/slideLayout"
    Target="../slideLayouts/slideLayout1.xml"/>
  <Relationship Id="rId2"
    Type="http://…/slideLayout"
    Target="../slideLayouts/slideLayout2.xml"/>
  <Relationship Id="rId3"
    Type="http://…/slideLayout"
    Target="../slideLayouts/slideLayout3.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be sldLayout.

[*Example*:

```
<p:sldLayout xmlns:p="…" matchingName="" type="title" preserve="1">
  <p:cSld name="Title Slide">
    …
  </p:cSld>
  <p:clrMapOvr>
    <a:masterClrMapping/>
  </p:clrMapOvr>
  <p:timing/>
  </p:sldLayout>
</p:sldMaster>
```

end example]

A Slide Layout part is permitted to have implicit relationships to the following parts defined by this Standard:

- Additional Characteristics (§15.2.1)
- Bibliography (§15.2.3)
- Custom XML Data Storage (§15.2.4)
- Slide Master (§13.3.10)
- Theme Override (§14.2.8)

- Thumbnail (§15.2.14)

A Slide Layout part is permitted to have explicit relationships to the following parts defined by this Standard:

- Audio (§15.2.2)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlink (§15.3).
- Image (§15.2.13)
- Video (§15.2.14)
- VML Drawing (§15.2.17)

A Slide Layout part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.10 Slide Master Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.slideMaster+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/slideMaster

An instance of this part type contains the master definition of formatting, text, and objects that appear on each slide in the presentation that is derived from this slide master.

A package shall contain one or more Slide Master parts, each of which shall be the target of an explicit relationship from the Presentation (§13.3.6) part, as well as an implicit relationship from any Slide Layout (§13.3.9) part where that slide layout is defined based on this slide master. Each can optionally be the target of a relationship in a Slide Layout (§13.3.9) part as well.

[*Example*: The following Presentation part-relationship item contains a relationship to the Slide Master part, which is stored in the ZIP item slideMasters/slideMaster1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/slideMaster" Target="slideMasters/slideMaster1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be sldMaster.

[*Example*:

```
<p:sldMaster xmlns:p="…">
  <p:cSld name="">
    …
  </p:cSld>
  <p:clrMap … />
</p:sldMaster>
```

end example]

A Slide Master part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Slide Master part is permitted to have implicit relationships to the following parts defined by this Standard:

- Additional Characteristics (§15.2.1)
- Bibliography (§15.2.3)
- Custom XML Data Storage (§15.2.4)
- Slide Layout (§13.3.9)
- Theme (§14.2.7)
- Thumbnail (§15.2.14)

A Slide Master part is permitted to have explicit relationships to the following parts defined by this Standard:

- Audio (§15.2.2)
- Chart (§14.2.1)
- Diagrams: Diagram Colors(§14.2.3), Diagram Data(§14.2.4), Diagram Layout Definition(§14.2.5) and Diagram Styles (§14.2.6)
- Embedded Control Persistence (§15.2.8)
- Embedded Object (§15.2.9)
- Embedded Package (§15.2.10)
- Hyperlink (§15.3).
- Image (§15.2.13)
- Video (§15.2.14)
- VML Drawing (§15.2.17)

A Slide Master part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.11 Slide Synchronization Data Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.slideUpdateInfo+xml

Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/slideUpdateInfo

An instance of this part type contains properties specifying the current state of a slide that is being synchronized with a version of that slide stored on a central server.

A package shall contain zero or one Slide Synchronization Data part for each slide stored in the presentation, and that part shall be the target of an implicit relationship from the corresponding Slide (§13.3.8) part.

[*Example*: The following Slide part-relationship item contains a relationship to the Slide Synchronization Data part, which is stored in the ZIP item slideUpdateInfo/slideUpdateInfo1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1" Type="http://…/slideUpdateInfo"
    Target="slideUpdateInfo/slideUpdateInfo1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be sldSyncPr.

[*Example*:

```
<p:sldSyncPr xmlns:p="…" serverSldId="1"
  serverSldModifiedTime="2006-08-12T01:31:08"
  clientInsertedTime="2006-08-12T01:34:11.227" />
```

end example]

A Slide Synchronization Data part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Slide Synchronization Data part is permitted to have implicit relationships to the following parts defined by this Standard:

- Slide Synchronization Server Location (§13.4)

A Slide Synchronization Data part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.12 User Defined Tags Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.tags+xml

Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/tags

An instance of this part type contains a set of user-defined properties for an object in a presentation (each property consisting of a name/value pair).

A package shall contain zero or more User Defined Tags parts, zero or one as the target of an explicit relationship from the corresponding Presentation (§13.3.6) or Slide (§13.3.8) part.

[*Example*: The following Slide part-relationship item contains a relationship to the User Defined Tags part, which is stored in the ZIP item tags/tag1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1" Type="http://…/tag"
    Target="tags/tag1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be tagLst.

[*Example*:

```
<p:tagLst xmlns:p="…" >
  <p:tag name="testTagName" val="testTagValue" />
</p:tagLst>
```

end example]

A User Defined Tags part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A User Defined Tags part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.3.13 View Properties Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.viewProps+xml
Root Namespace:	http://schemas.openxmlformats.org/presentationml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/viewProps

An instance of this part type contains display properties for this presentation.

A package shall contain zero or one View Properties part, and if it exists, that part shall be the target of an implicit relationship from the Presentation (§13.3.6) part.

[*Example*: The following Presentation part-relationship item contains a relationship to the View Properties part, which is stored in the ZIP item viewProps.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId7"
    Type="http://…/viewProps" Target="viewProps.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be viewPr.

[*Example*:

```
<p:viewPr xmlns:p="…" …>
  <p:normalViewPr showOutlineIcons="0">
    …
  </p:normalViewPr>
  <p:slideViewPr>
    …
  </p:slideViewPr>
  <p:outlineViewPr>
    …
  </p:outlineViewPr>
  <p:notesTextViewPr>
    …
  </p:notesTextViewPr>
  <p:gridSpacing cx="78028800" cy="78028800"/>
</p:viewPr>
```

end example]

A View Properties part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A View Properties part shall not have implicit or explicit relationships to any other part defined by this Standard.

13.4 HTML Publish Location

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/ htmlPubSaveAs

When a presentation specifies an external location to which an optional copy might be pushed in the HTML format, this relationship shall be used to target the location where the HTML copy of the presentation is published.

A package shall contain one HTML Publish Location relationship for each slide linked with an HTML publish location, and that relationships shall be an explicit relationship from the corresponding Presentation Properties (§13.3.7) part.

[*Example*: A Presentation Properties part, which stores an HTML Publish Location of http://www.openxmlformats.org/test.htm will contain the following relationship in that part's relationship part:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/htmlPubSaveAs"
    Target="http://www.openxmlformats.org/test.htm" type=”External”/>
</Relationships>
```

end example]

An HTML publish location shall be located external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `External`).

13.5 Slide Synchronization Server Location

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/slideUpdateUrl

When a slide is being synchronized with a copy stored on a remote server, this relationship shall be used to target the location where the server copy of the slide is stored.

A package shall contain one Slide Synchronization Server Location relationship for each slide linked with server data, and that relationships shall be an implicit relationship from the corresponding Slide Synchronization Data (§13.3.11) part.

[*Example*: A Slide Synchronization Data part that stores information about a slide that is synchronized with a server located at http://www.openxmlformats.org/slides/ will contain the following relationship in that part's relationship part item:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/slideupdateUrl"
    Target="http://www.openxmlformats.org/slides/" type=”External”/>
</Relationships>
```

end example]

A slide synchronization server location shall be located external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `External`).

14. DrawingML

The relationship items and parts defined in this clause are used by one or more of WordprocessingML (§10), SpreadsheetML (§12), and PresentationML (§13) environments.

14.1 Glossary of DrawingML-Specific Terms

diagram — A picture or graphical representation that is displayed using a related set of color, data, layout, and style parts. Examples of diagram types are cycle, organization chart, pyramid, target, and Venn.

14.2 Part Summary

The subclauses subordinate to this one describe in detail each of the part types specific to DrawingML.

[*Note*: For convenience, information from those subclauses is summarized in the following table:

Part	Relationship Target of	Root Element	Ref.
Chart	WordprocessingML: Main Document SpreadsheetML: Drawings PresentationML: Handout Master, Notes Master, Notes Slide, Slide Layout, Slide Master, Slide All: Chart Drawing	chartSpace	§14.2.1
Chart Drawing	All: Chart	userShapes	§14.2.2
Diagram Colors	WordprocessingML: Main Document SpreadsheetML: Drawings PresentationML: Handout Master, Notes Master, Notes Slide, Slide Layout, Slide Master, Slide	colorsDef	§14.2.3
Diagram Data	WordprocessingML: Main Document SpreadsheetML: Drawings PresentationML: Handout Master, Notes Master, Notes Slide, Slide Layout, Slide Master, Slide	dataModel	§14.2.4
Diagram Layout Definition	WordprocessingML: Main Document SpreadsheetML: Drawings PresentationML: Handout Master, Notes Master, Notes Slide, Slide Layout, Slide Master, Slide	layoutDef	§14.2.5

Part	Relationship Target of	Root Element	Ref.
Diagram Style	WordprocessingML: Main Document SpreadsheetML: Drawings PresentationML: Handout Master, Notes Master, Notes Slide, Slide Layout, Slide Master, Slide	styleDef	§14.2.6
Theme	WordprocessingML: Main Document SpreadsheetML: Workbook PresentationML: Handout Master, Notes Master, Presentation, Slide Master	officeStyleSheet	§14.2.7
Theme Override	PresentationML: Notes Slide, Slide, Slide Layout	themeOverride	§14.2.8
Table Styles	PresentationML: Presentation	tblStyleLst	§14.2.9

end note]

14.2.1 Chart Part

Content Type:	application/vnd.openxmlformats-officedocument.drawingml.chart+xml
Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/chart
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/chart

An instance of this part type describes a chart.

A package shall contain a Chart part for each chart in the document. In a WordprocessingML document, each such part shall be the target of an explicit relationship in a Main Document (§11.3.10) part. In a SpreadsheetML document, each such part shall be the target of an explicit relationship in a Drawings (§12.3.8) part. In a PresentationML document, each such part shall be the target of an explicit relationship in a Handout Master (§13.3.3), Notes Master (§13.3.4), Notes Slide (§13.3.5), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part. This part is permitted to also be the target of an explicit relationship in a Chart Drawing (§14.2.2) part, if the chart that points at this Chart Drawing part is the target of a relationship from a Chartsheet part. In other words, the only time a chart can embed another chart is if the parent chart is part of a chartsheet.

[*Example*: The following Main Document part-relationship item contains relationships to two Chart parts, which are stored in the ZIP items ../charts/chart*N*.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/chart" Target="charts/chart1.xml"/>
  <Relationship Id="rId5"
    Type="http://…/chart" Target="charts/chart2.xml"/>
</Relationships>
```

The following Drawings part-relationship item contains a relationship to a Chart part, which is stored in the ZIP item ../charts/chart1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/relationships/chart" Target="../charts/chart1.xml"/>
</Relationships>
```

The following Slide part-relationship item contains relationships to two Chart parts, which are stored in the ZIP items ../charts/chart*N*.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/chart" Target="../charts/chart1.xml"/>
  <Relationship Id="rId5"
    Type="http://…/chart" Target="../charts/chart2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be chartSpace.

[*Example*: chart1.xml contains the following clustered bar chart:

```
<c:chartSpace …>
  <c:chart>
    <c:title>
      …
    </c:title>
    <c:plotArea>
      <c:layout>
        …
      </c:layout>
      <c:barChart>
        …
      </c:barChart>
    </c:plotArea>
```

```
            <c:legend>
          …
        </c:legend>
      </c:chart>
      …
    </c:chartSpace>
```

end example]

For WordprocessingML and PresentationML documents, the data for a chart is not stored in the Chart part directly. Instead, it shall be stored in an embedded SpreadsheetML package (§12.2) targeted by an Embedded Package (§15.2.10) part specified by that Chart part. For SpreadsheetML documents, the data for a chart is stored directly in the Drawing's parent worksheet; no embedded SpreadsheetML package shall be used.

A Chart part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Chart part is permitted to have explicit relationships to the following parts defined by this Standard:

- Chart Drawing (§14.2.2)
- Embedded Package (§15.2.10)

A Chart part shall not have any implicit or explicit relationships to any other part defined by this Standard.

14.2.2 Chart Drawing Part

Content Type:	application/vnd.openxmlformats-officedocument.drawingml.chartshapes+xml
Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/chart
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/chartUserShapes

An instance of this part type contains all basic drawing elements (shapes) which are explicitly associated with this chart. These drawing elements are automatically moved with the chart when it is moved and resized when the chart is resized.

A package is permitted to contain one Chart Drawing part per chart part, and each such part shall be the target of an explicit relationship from a Chart (§14.2.1) part.

[*Example*: The following Chart part-relationship item contains a relationship to a Chart Drawing part, which is stored in the ZIP item ../drawings/drawing1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/chartUserShapes" Target="../drawings/drawing1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be userShapes.

[*Example*:

```
<c:userShapes xmlns:cdr="…" xmlns:c="…">
  <cdr:relSizeAnchor>
    …
  </cdr:relSizeAnchor>
</c:userShapes>
```

end example]

A Chart Drawing part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Chart Drawing part is permitted to have explicit relationships to the following parts defined by this Standard:

- Chart (§14.2.1)

A Chart Drawing part shall not have any implicit or explicit relationships to any other part defined by this Standard.

14.2.3 Diagram Colors Part

Content Type:	application/vnd.openxmlformats-officedocument.drawingml.diagramColors+xml
Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/diagram
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/diagramColors

An instance of this part type contains color information for a diagram.

A package shall contain exactly one Diagram Colors part per diagram. Each Diagram Colors part shall be the target of an explicit relationship in a WordprocessingML Main Document (§11.3.10), SpreadsheetML Drawings (§12.3.8), or PresentationML Slide (§13.3.8) part.

[*Example*: The following SpreadsheetML Drawings part-relationship item contains a relationship to two Diagram Colors parts, which are stored in the ZIP items ../graphics/colors*N*.xml.

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
     Type="http://…/diagramColors" Target="../graphics/colors1.xml"/>
  <Relationship Id="rId8"
    Type="http://…/diagramColors" Target="../graphics/colors2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be colorsDef.

[*Example*: colors1.xml contains the following:

```
<cs:colorsDef xmlns:cs="…" uniqueId="…" minVer="12.0">
  <cs:title lang="" val="Primary Accent 2"/>
  <cs:desc lang="" val="Primary Accent 2"/>
  <cs:catLst>
    <cs:cat type="accent1" pri="11200"/>
  </cs:catLst>
  <cs:styleLbl …>
    …
  </cs:styleLbl>
  …
  <cs:styleLbl …>
    …
  </cs:styleLbl>
</cs:colorsDef>
```

end example]

A Diagram Colors part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Diagram Colors part shall not have implicit or explicit relationships to any other part defined by this Standard.

14.2.4 Diagram Data Part

Content Type:	application/vnd.openxmlformats-officedocument.drawingml.diagramData+xml
Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/diagram
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/diagramData

An instance of this part type contains the semantic data for a diagram.

A package shall contain exactly one Diagram Data part per diagram. Each Diagram Data part shall be the target of an explicit relationship in a WordprocessingML Main Document (§11.3.10); a SpreadsheetML Drawings part (§12.3.8); or a PresentationML Handout Master (§13.3.3), Notes Master (§13.3.4), Notes Slide (§13.3.5), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part.

[*Example*: The following SpreadsheetML Drawings part-relationship item contains a relationship to two Diagram Data parts, which are stored in the ZIP items ../graphics/data*N*.xml.

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/diagramData" Target="../graphics/data1.xml"/>
  <Relationship Id="rId5"
    Type="http://…/diagramData" Target="../graphics/data2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be dataModel.

[*Example*: data1.xml contains the following:

```
<dm:dataModel xmlns:dm="…">
  <dm:ptLst>
    …
  </dm:ptLst>
  <dm:cxnLst>
    …
  </dm:cxnLst>
  <dm:bg/>
  <dm:whole/>
</dm:dataModel>
```

end example]

A Diagram Data part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Diagram Data part is permitted to have explicit relationships to the following parts defined by this Standard:

- Image (§15.2.13)

A Diagram Data part shall not have any implicit or explicit relationships to other parts defined by this Standard.

14.2.5 Diagram Layout Definition Part

Content Type:	application/vnd.openxmlformats-officedocument.drawingml.diagramLayout+xml

Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/diagram
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/diagramLayout

An instance of this part type is a template that describes how diagram-related data is mapped to a shape.

A package shall contain exactly one Diagram Layout Definition part per diagram. Each Layout Definition part shall be the target of an explicit relationship from a WordprocessingML Main Document (§11.3.10); a SpreadsheetML Drawings part (§12.3.8); or a PresentationML Handout Master (§13.3.3), Notes Master (§13.3.4), Notes Slide (§13.3.5), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part. If a document contains multiple diagrams having the same graphic layout definition, each of those diagrams shall have its own copy of that Diagram Layout Definition part.

[*Example*: The following SpreadsheetML Drawings part-relationship item contains a relationship to two Diagram Layout Definition parts, which are stored in the ZIP items ../graphics/layout*N*.xml.

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/diagramLayout" Target="../graphics/layout1.xml"/>
  <Relationship Id="rId6"
    Type="http://…/diagramLayout" Target="../graphics/layout2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be layoutDef.

[*Example*: layout1.xml contains the following:

```
<lo:layoutDef xmlns:lo="…" uniqueId="…2" minVer="12.0" defStyle="">
  <lo:title lang="" val="Hierarchy 2"/>
  <lo:desc lang="" val=""/>
  <lo:catLst>
    <lo:cat type="hierarchy" pri="2000"/>
  </lo:catLst>
  <lo:sampData>
    …
  </lo:sampData>
  <lo:styleData>
    …
  </lo:styleData>
```

```
    <lo:clrData>
      …
    </lo:clrData>
    <lo:layoutNode name="Name0" styleLbl="" moveWith="">
      …
     </lo:layoutNode>
  </lo:layoutDef>
```

end example]

A Diagram Layout Definition part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Diagram Layout Definition part is permitted to have explicit relationships to the following parts and items defined by this Standard:

- Image (§15.2.13)

A Diagram Layout Definition part shall not have any implicit or explicit relationships to other parts defined by this Standard.

14.2.6 Diagram Style Part

Content Type:	application/vnd.openxmlformats-officedocument.drawingml.diagramStyle+xml
Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/diagram
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/diagramQuickStyle

An instance of this part type maps diagram semantic information to a document's theme.

A package shall contain exactly one Diagram Style part per diagram. Each Style part shall be the target of an explicit relationship from a WordprocessingML Main Document (§11.3.10); a SpreadsheetML Drawings part (§12.3.8); or a PresentationML Handout Master (§13.3.3), Notes Master (§13.3.4), Notes Slide (§13.3.5), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part.

[*Example*: The following SpreadsheetML Drawings part-relationship item contains a relationship to two Diagram Style parts, which are stored in the ZIP items ../graphics/quickStyle*N*.xml.

```
<Relationships xmlns="…">
  <Relationship Id="rId3"
    Type="http://…/diagramQuickStyle"
    Target="../graphics/quickStyle1.xml"/>
  <Relationship Id="rId7"
    Type="http://…/diagramQuickStyle"
    Target="../graphics/quickStyle2.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be styleDef.

[*Example*: quickStyle1.xml contains the following:

```
<qs:styleDef xmlns:qs="…" uniqueId="…" minVer="12.0">
  <qs:title lang="" val="Style 2"/>
  <qs:desc lang="" val="Style 2"/>
  <qs:catLst>
    <qs:cat type="simple" pri="10200"/>
  </qs:catLst>
  <qs:scene3d>
    …
  </qs:scene3d>
  <qs:style>
    …
  </qs:style>
  <qs:styleLbl name="…">
    …
  </qs:styleLbl>
  …
  <qs:styleLbl name="…">
    …
  </qs:styleLbl>
</qs:styleDef>
```

end example]

A Diagram Style part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Diagram Style part shall not have implicit or explicit relationships to other parts defined by this Standard.

14.2.7 Theme Part

Content Type:	application/vnd.openxmlformats-officedocument.theme+xml

Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/theme

An instance of this part type contains information about a document's *theme*, which is a combination of *color scheme*, *font scheme*, and *format scheme* (the latter also being referred to as *effects*). For a WordprocessingML document, the choice of theme affects the color and style of headings, among other things. For a SpreadsheetML document, the choice of theme affects the color and style of cell contents and charts, among other things. For a PresentationML document, the choice of theme affects the formatting of slides, handouts, and notes via the associated master, among other things.

A WordprocessingML or SpreadsheetML package shall contain zero or one Theme part, which shall be the target of an implicit relationship in a Main Document (§11.3.10) or Workbook (§12.3.23) part. A PresentationML package shall contain zero or one Theme part per Handout Master (§13.3.3), Notes Master (§13.3.4), Slide Master (§13.3.10) or Presentation (§13.3.6) part via an implicit relationship.

[*Example*: The following WordprocessingML Main Document part-relationship item contains a relationship to the Theme part, which is stored in the ZIP item theme/theme1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/theme" Target="theme/theme1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be officeStyleSheet.

[*Example*: theme1.xml contains the following, where the name attributes of the clrScheme, fontScheme, and fmtScheme elements correspond to the document's color scheme, font scheme, and format scheme, respectively:

```
<a:officeStyleSheet xmlns:a="…">
  <a:baseStyles>
    <a:clrScheme name="…">
      …
    </a:clrScheme>
    <a:fontScheme name="…">
      …
    </a:fontScheme>
```

```
      <a:fmtScheme name="…">
        …
      </a:fmtScheme>
    </a:baseStyles>
    <a:objectDefaults/>
  </a:officeStyleSheet>
```

end example]

A Theme part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Theme part is permitted to contain explicit relationships to the following parts defined by this Standard:

- Image (§15.2.13)

A Theme part shall not have any implicit or explicit relationships to other parts defined by this Standard.

14.2.8 Theme Override Part

Content Type:	application/vnd.openxmlformats-officedocument.themeOverride+xml
Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/themeOverride

An instance of this part type contains information about an object's *theme override*, which are overrides to the *color scheme*, *font scheme*, and *format scheme* (the latter also being referred to as *effects*) for a particular slide, notes slide, or handout.

A PresentationML package shall contain zero or one Theme Override part per Notes Slide (§13.3.5), Slide (§13.3.8), or Slide Layout (§13.3.9) part via an implicit relationship.

[*Example*: The following WordprocessingML Main Document part-relationship item contains a relationship to the Theme part, which is stored in the ZIP item theme/theme1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/themeOverride" Target="theme/themeoverride1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be ossOverride.

[*Example*:

```
<a:ossOverride xmlns:a="…" >
  …
</a:ossOverride>
```

end example]

A Theme Override part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Theme Override part shall not contain implicit or explicit relationships to other parts defined by this Standard.

14.2.9 Table Styles Part

Content Type:	application/vnd.openxmlformats-officedocument.presentationml.tableStyles+xml
Root Namespace:	http://schemas.openxmlformats.org/drawingml/2006/main
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/tableStyles

An instance of this part type contains information about the table styles used by tables in this presentation. A table style defines characteristics such as row and column colors, heading row colors, and text.

A PresentationML package shall contain no more than one Table Styles part per Presentation (§13.3.6) part via an implicit relationship.

[*Example*: The following Presentation part-relationship item contains a relationship to a Table Styles part, which is stored in the ZIP item tableStyles.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/tableStyles" Target="tableStyles.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be tblStyleLst.

[*Example*: tablestyles.xml contains the following:

```
<a:tblStyleLst xmlns:a="…">
  <a:tblStyle>
    …
  </a:tblStyle>
</a:tblStyleLst>
```

end example]

A Table Styles part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Table Styles part shall not contain implicit or explicit relationships to other parts defined by this Standard.

15. Shared

The relationship items and parts defined in this clause are used by one or more of WordprocessingML (§10), SpreadsheetML (§12), and PresentationML (§13) environments.

15.1 Glossary of Shared Terms

control — A region of active content within an Office Open XML document.

15.2 Part Summary

The subclauses subordinate to this one describe in detail each of the shared part types.

[*Note*: For convenience, information from those subclauses is summarized in the following table:

Part	Relationship Target of	Root Element	Ref.
Additional Characteristics	Numerous PresentationML, SpreadsheetML, and WordprocessingML parts	Characteristics	§15.2.1
Audio	Numerous PresentationML, SpreadsheetML, and WordprocessingML parts	Not applicable	§15.2.2
Bibliography	Numerous PresentationML, SpreadsheetML, and WordprocessingML parts	Sources	§15.2.3
Custom XML Data Storage	Numerous PresentationML, SpreadsheetML, and WordprocessingML parts	Not applicable	§15.2.4
Custom XML Data Storage Properties	Custom XML Data Storage	datastoreItem	§15.2.5
Digital Signature Origin	WordprocessingML, SpreadsheetML, or PresentationML package	Not applicable	§15.2.6
Digital Signature XML Signature	Digital Signature Origin	Signature	§15.2.7
Embedded Control Persistence	Numerous PresentationML, SpreadsheetML, and WordprocessingML parts	Not applicable	§15.2.8
Embedded Object	Numerous PresentationML, SpreadsheetML, and WordprocessingML parts	Not applicable	§15.2.9

Part	Relationship Target of	Root Element	Ref.
Embedded Package	Numerous PresentationML, SpreadsheetML, and WordprocessingML parts	Not applicable	§15.2.10
File Properties, Extended	WordprocessingML, SpreadsheetML, or PresentationML package	Properties	§ 15.2.11.3
File Properties, Core	WordprocessingML, SpreadsheetML, or PresentationML package	coreProperties	§15.2.11.1
File Properties, Custom	WordprocessingML, SpreadsheetML, or PresentationML package	properties	§15.2.11.2
Font	WordprocessingML Font Table part, PresentationML Presentation part	Not applicable	§15.2.12
Image	Numerous PresentationML, SpreadsheetML, and WordprocessingML parts	Not applicable	§15.2.13
Printer Settings	SpreadsheetML Chartsheet, Dialogsheet, Worksheet parts, WordprocessingML Main Document or Glossary Document parts	Not applicable	§15.2.14
Thumbnail	WordprocessingML, SpreadsheetML, or PresentationML package	Not applicable	§15.2.14
Video part	Numerous PresentationML and WordprocessingML parts	Not applicable	§15.2.16

end note]

15.2.1 Additional Characteristics Part

Content Type:	application/xml
Root Namespace:	http://schemas.openxmlformats.org/officeDocument/2006/additionalCharacteristics
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/customXml

An instance of this part type contains information about additional characteristics of the producer that generated the document, when those characteristics cannot be specified using elements defined by this Standard.

A package is permitted to contain zero or one Additional Characteristics parts, and each such part shall be the target of an implicit relationship from a Main Document (§11.3.10) part in a WordprocessingML package; a Workbook (§12.3.23) part in a SpreadsheetML package; or a Handout Master (§13.3.3) , Notes Master (§13.3.4), Notes Slide (§13.3.5), Presentation (§13.3.6), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part in a PresentationML package.

[*Example*: The following Main Document part-relationship item contains a relationship to an Additional Characteristics part, which is stored in the ZIP item ../customXML/item2.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/customXmlData" Target="../customXML/item2.xml"/>
</Relationships>
```

end example]

An Additional Characteristics part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

An Additional Characteristics part is permitted to have implicit relationships to the following parts defined by this Standard:

- Custom XML Data Storage Properties (§15.2.5)

An Additional Characteristics part shall not have implicit or explicit relationships to any other part defined by this Standard.

15.2.2 Audio Part

<table>
<tr><td>Content Type:</td><td>Any supported audio type.

[Note: Some example content types are:
<table>
<tr><td>audio/aiff</td><td>http://developer.apple.com/documentation/QuickTime/INMAC/SOUND/imsoundmgr.30.htm</td></tr>
<tr><td>audio/midi</td><td>http://www.midi.org/about-midi/specinfo.shtml</td></tr>
<tr><td>audio/x-ms-wax</td><td>http://msdn.microsoft.com/library/en-us/wmplay10/mmp_sdk/asx_elementsintro.asp</td></tr>
</table>
end note]</td></tr>
<tr><td>Root Namespace:</td><td>not applicable</td></tr>
<tr><td>Source Relationship:</td><td>http://schemas.openxmlformats.org/officeDocument/2006/relationships/audio</td></tr>
</table>

An instance of this part type contains an audio file.

A PresentationML package is permitted to contain zero or more Sound parts, each of which shall be the target of a relationship in a Handout Master (§13.3.3), Notes Slide (§13.3.5), Notes Master (§13.3.4), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part-relationship item. [*Example*: The following Slide part-relationship item contains a relationship to a Sound part, which is stored as the file E:\Beethoven's Symphony No. 9.wma:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/audio/x-ms-wma"
    Target="file:///E:\Beethoven's%20Symphony%20No.%209.wma"
    TargetMode="External"/>
</Relationships>
```

end example]

An Audio part may be located within or external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element may be `Internal` or `External`).

An Audio part is not stored as XML; instead, it involves a relationship target that is an audio clip.

An Audio part shall not have implicit or explicit relationships to other parts defined by this Standard.

15.2.3 Bibliography Part

Content Type:	application/xml
Root Namespace:	http://schemas.openxmlformats.org/officeDocument/2006/bibliography
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/customXml

An instance of this part type contains bibliographic data for the current package.

A package is permitted to contain zero or one Bibliography part, and each such part shall be the target of an implicit relationship in a Main Document (§11.3.10) part in a WordprocessingML package; a Workbook (§12.3.23) part in a SpreadsheetML package; or a Handout Master (§13.3.3) , Notes Master (§13.3.4), Notes Slide (§13.3.5), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part in a PresentationML package.

[*Example*: The following Main Document part-relationship item contains a relationship to a Bibliography part, which is stored in the ZIP item ../customXML/bib1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/customXml" Target="../customXML/bib1.xml"/>
</Relationships>
```

end example]

A Bibliography part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Bibliography part is permitted to have implicit relationships to the following parts defined by this Standard:

- Custom XML Data Storage Properties (§15.2.5)

A Bibliography part shall not have implicit or explicit relationships to any other part defined by this Standard.

15.2.4 Custom XML Data Storage Part

Content Type:	application/xml
Root Namespace:	any XML allowed
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/customXml

An instance of this part type can contain arbitrary XML. As such, an instance of this part can be used to roundtrip arbitrary custom XML data with this package.

A package is permitted to contain one or more Custom XML Data Storage parts, and each such part shall be the target of an implicit relationship in a Main Document (§11.3.10) part in a WordprocessingML package; a Workbook (§12.3.23) part in a SpreadsheetML package; or a Handout Master (§13.3.3) , Notes Master (§13.3.4), Notes Slide (§13.3.5), Presentation (§13.3.6), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part in a PresentationML package.

[*Example*: The following Main Document part-relationship item contains a relationship to a Custom XML Data Storage part, which is stored in the ZIP item ../customXML/item1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/customXmlData" Target="../customXML/item1.xml"/>
</Relationships>
```

end example]

A Custom XML Data Storage part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Custom XML Data Storage part is permitted to have implicit relationships to the following parts defined by this Standard:

- Custom XML Data Storage Properties (§15.2.5)

A Custom XML Data Storage part shall not have implicit or explicit relationships to any other part defined by this Standard.

15.2.5 Custom XML Data Storage Properties Part

Content Type:	application/vnd.openxmlformats-officedocument.customXmlProperties+xml
Root Namespace:	http://schemas.openxmlformats.org/officeDocument/2006/customXmlDataProps
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/customXmlProps

An instance of this part type contains the set of properties which are specified for this custom XML data. These properties consist of a unique ID for the storage, as well as information on the set of XML schemas used by this custom XML data storage.

A package is permitted to contain zero or more Custom XML Data Storage Properties parts, and each such part shall be the target of an implicit relationship from a Custom XML Data Storage (§15.2.4) part.

[*Example*: The following Custom XML Data Storage part-relationship item contains a relationship to a Custom XML Data Storage Properties part, which is stored in the ZIP item itemProps1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/customXmlProps" Target="itemProps1.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be datastoreItem.

[*Example*:

```
<ds:datastoreItem ds:itemID="{D85…53A}" xmlns:ds="…"/> \
```

end example]

A Custom XML Data Storage Properties part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be Internal).

A Custom XML Data Storage Properties part shall not have implicit or explicit relationships to other parts defined by this Standard.

15.2.6 Digital Signature Origin Part

Content Type:	application/vnd.openxmlformats-package.digital-signature-origin

Root Namespace:	not applicable
Source Relationship:	http://schemas.openxmlformats.org/package/2006/relationships/digital-signature/origin

The Digital Signature Origin part is the starting point for navigating through the signatures in a package.

This part shall have no contents.

A package is permitted to contain zero or one Digital Signature Origin part in a package and it shall the target of a relationship from the package-relationship item for a WordprocessingML, SpreadsheetML, or PresentationML package.

[*Example*: The following package-relationship item contains a relationship to a Digital Signature Origin part, which is stored in the ZIP item origin.sigs:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/origin" Target="../origin.sigs"/>
</Relationships>
```

end example]

A Digital Signature Origin part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Digital Signature Origin part is permitted to have implicit relationships to the following parts defined by this Standard:

- Digital Signature XML Signature (§15.2.7)

A Digital Signature Origin part shall not have implicit or explicit relationships to any other part defined by this Standard.

15.2.7 Digital Signature XML Signature Part

Content Type:	application/vnd.openxmlformats-package.digital-signature-xmlsignature+xml
Root Namespace:	http://schemas.openxmlformats.org/package/2006/digital-signature
Source Relationship:	http://schemas.openxmlformats.org/package/2006/relationships/digital-signature/signature

The Digital Signature XML Signature part contains digital signature markup.

A package is permitted to contain zero or more Digital Signature XML Signature parts, one for each digital signature in a package, and each of these shall be the target of an implicit relationship from the Digital Signature Origin (§15.2.6) part.

[*Example*: The following Digital Signature Origin part-relationship item contains a relationship to a Digital Signature XML Signature part, which is stored in the ZIP item sig1.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/signature" Target="../sig1.xml"/>
</Relationships>
```

end example]

The root element for this part shall be Signature.

[*Example*:

```
<Signature xmlns="…" Id="idPackageSignature" >
  …
</Signature>
```

end example]

A Digital Signature XML Signature part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Digital Signature XML Signature part shall not have implicit or explicit relationships to any part defined by this Standard.

15.2.8 Embedded Control Persistence Part

Content Type:	Any supported control type. [*Note*: There are a number of possible control types. One example of a potential control type would be an Active X control, which would use the following content type: `application/vnd.ms-office.activeX+xml`. *end note*]
Root Namespace:	not applicable
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/control

An instance of this part contains information about an embedded control in the package. This information is provided by the specified control when asked to persist.

A package is permitted to contain one or more Embedded Control Persistence parts, and each such part shall be the target of an explicit relationship in an Endnotes (§11.3.4), Footer (§11.3.6), Footnotes (§11.3.7), Header (§11.3.9), or Main Document (§11.3.10) part-relationship item in a WordprocessingML package; a Worksheet part (§12.3.24) 15.2.17in a SpreadsheetML package; or a Handout Master (§13.3.3), Notes Slide (§13.3.5), Notes Master (§13.3.4), Slide (§13.3.8), Slide Layout (§13.3.9), Slide Master (§13.3.10) part-relationship item in a PresentationML package.

The content type of this part shall determine the format and contents of the embedded control.

[*Example*: The following example shows the persistence that could be used for an embedded control which is a Java applet within a WordprocessingML document:

```
<w:p>
  <w:r w:rsidR="005810E1">
    <w:object w:dxaOrig="1440" w:dyaOrig="1440">
      <v:shapetype id="_x0000_t75" coordsize="21600,21600" o:spt="75"
o:preferrelative="t" path="m@4@5l@4@11@9@11@9@5xe" filled="f" stroked="f">
        <v:stroke joinstyle="miter" />
        <v:formulas>
          <v:f eqn="if lineDrawn pixelLineWidth 0" />
          <v:f eqn="sum @0 1 0" />
          <v:f eqn="sum 0 0 @1" />
          <v:f eqn="prod @2 1 2" />
          <v:f eqn="prod @3 21600 pixelWidth" />
          <v:f eqn="prod @3 21600 pixelHeight" />
          <v:f eqn="sum @0 0 1" />
          <v:f eqn="prod @6 1 2" />
          <v:f eqn="prod @7 21600 pixelWidth" />
          <v:f eqn="sum @8 21600 0" />
          <v:f eqn="prod @7 21600 pixelHeight" />
          <v:f eqn="sum @10 21600 0" />
        </v:formulas>
        <v:path o:extrusionok="f" gradientshapeok="t" o:connecttype="rect" />
        <o:lock v:ext="edit" aspectratio="t" />
      </v:shapetype>
      <v:shape id="_x0000_i1027" type="#_x0000_t75"
style="width:1in;height:24pt" o:ole="">
        <v:imagedata r:id="rId4" o:title="" />
      </v:shape>
      <w:control r:id="rId5" w:name="CommandButton1" w:shapeid="_x0000_i1027"
/>
    </w:object>
  </w:r>
</w:p>
```

The relationship type for rId5 is: http://schemas.openxmlformats.org/officeDocument/2006/relationships/control

The XML content of the part referenced by rId5 could be:

```
<applet xlink:href="../../../../Program%20Files/Application"
xlink:type="simple" xlink:show="embed" xlink:actuate="onLoad"
code="CalculateApplet.class" may-script="false"/>
```

end example]

[*Example*: The following example shows the persistence that could be used for an embedded control which is an ActiveX control within a WordprocessingML document:

```
<w:p>
  <w:r w:rsidR="005810E1">
    <w:object w:dxaOrig="1440" w:dyaOrig="1440">
      <v:shapetype id="_x0000_t75" coordsize="21600,21600" o:spt="75"
o:preferrelative="t" path="m@4@5l@4@11@9@11@9@5xe" filled="f" stroked="f">
        <v:stroke joinstyle="miter" />
        <v:formulas>
          <v:f eqn="if lineDrawn pixelLineWidth 0" />
          <v:f eqn="sum @0 1 0" />
          <v:f eqn="sum 0 0 @1" />
          <v:f eqn="prod @2 1 2" />
          <v:f eqn="prod @3 21600 pixelWidth" />
          <v:f eqn="prod @3 21600 pixelHeight" />
          <v:f eqn="sum @0 0 1" />
          <v:f eqn="prod @6 1 2" />
          <v:f eqn="prod @7 21600 pixelWidth" />
          <v:f eqn="sum @8 21600 0" />
          <v:f eqn="prod @7 21600 pixelHeight" />
          <v:f eqn="sum @10 21600 0" />
        </v:formulas>
        <v:path o:extrusionok="f" gradientshapeok="t" o:connecttype="rect" />
        <o:lock v:ext="edit" aspectratio="t" />
      </v:shapetype>
      <v:shape id="_x0000_i1027" type="#_x0000_t75"
style="width:1in;height:24pt" o:ole="">
        <v:imagedata r:id="rId4" o:title="" />
      </v:shape>
      <w:control r:id="rId5" w:name="CommandButton1" w:shapeid="_x0000_i1027"
/>
    </w:object>
  </w:r>
```

```
</w:p>
```

The relationship type for rId5 is: `http://schemas.openxmlformats.org/officeDocument/2006/relationships/control`

The content type of the part referenced by rId5 could be: `application/vnd.ms-office.activeX+xml`

The XML content of the part referenced by rId5 could be:

```
<ax:ocx ax:classid="{D7053240-CE69-11CD-A777-00DD01143C57}"
    ax:persistence="persistPropertyBag"
    xmlns:ax="http://schemas.microsoft.com/office/2006/activeX">
  <ax:ocxPr ax:name="Caption" ax:value="CommandButton1" />
  <ax:ocxPr ax:name="Size" ax:value="2540;847" />
  <ax:ocxPr ax:name="FontName" ax:value="Calibri" />
  <ax:ocxPr ax:name="FontHeight" ax:value="225" />
  <ax:ocxPr ax:name="FontCharSet" ax:value="0" />
  <ax:ocxPr ax:name="FontPitchAndFamily" ax:value="2" />
  <ax:ocxPr ax:name="ParagraphAlign" ax:value="3" />
</ax:ocx>
```

end example]

An Embedded Control Persistence part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

An Embedded Control Persistence part shall not have any implicit or explicit relationships to other parts defined by this Standard.

15.2.9 Embedded Object Part

Content Type:	application/vnd.openxmlformats-officedocument.oleObject
Root Namespace:	not applicable
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/oleObject

An instance of this part type can contain an embedded object produced by any embedded object server.

A package is permitted to contain zero or more Embedded Object parts, and each such part shall be the target of an explicit relationship from a Comments (§11.3.2), Endnotes (§11.3.4), Footer (§11.3.6), Footnotes (§11.3.7), Header (§11.3.9), or Main Document (§11.3.10) part in a WordprocessingML package; a Worksheet part (§12.3.24) in a SpreadsheetML package; or a Handout Master (§13.3.3), Notes Slide (§13.3.5), Notes Master (§13.3.4), Slide (§13.3.8), Slide Layout (§13.3.9), Slide Master (§13.3.10) part in a PresentationML package.

A WordprocessingML document package is permitted to contain zero or more Embedded Object parts, each of which shall be the target of a relationship in a Main Document part-relationship item. Each Embedded Object part shall have an associated image, which appears in the document as a placeholder for the corresponding embedded object.

[*Example*: Consider the case in which a WordprocessingML document has embedded in it one video object and one audio object. The following Main Document part-relationship item contains relationships to two Embedded parts (one each for the video and audio), which are stored in the ZIP items embeddings/embeddedObject*N*.bin:

```
<Relationships xmlns="…">
  <Relationship Id="rId5"
    Type="http://…/oleObject" Target="embeddings/embeddedObject1.bin"/>
  <Relationship Id="rId7"
    Type="http://…/oleObject" Target="embeddings/embeddedObject2.bin"/>
  <Relationship Id="rId4"
    Type="http://…/image" Target="media/image1.png"/>
  <Relationship Id="rId6"
    Type="http://…/image" Target="media/image2.png"/>
</Relationships>
```

example]

A SpreadsheetML document package is permitted to contain zero or more Embedded Object parts, each of which shall be the target of a relationship in a Worksheet part-relationship item.

[*Example*: Consider the case in which a SpreadsheetML document has embedded in it one video object and one audio object on one worksheet, and another audio object embedded in another worksheet. The following Worksheet Document part-relationship item contains relationships to two Embedded Object parts (one each for the video and audio), which are stored in the ZIP items ../embeddings/embeddedObject*N*.bin:

```
<Relationships xmlns="…">
   <Relationship Id="rId2"
     Type="http://…/oleObject" Target="../embeddings/embeddedObject1.bin"/>
  <Relationship Id="rId3"
    Type="http://…/oleObject" Target="../embeddings/embeddedObject2.bin"/>
</Relationships>
```

end example]

A PresentationML document package is permitted to contain zero or more Embedded Object parts, each of which shall be the target of a relationship in a Slide part-relationship item.

[*Example*: Consider the case in which a PresentationML document has embedded in it one video object and one audio object on one slide, and another audio object embedded on another slide. The following Slide part-

relationship item contains relationships to two Embedded Object parts (one each for the video and audio), which are stored in the ZIP items ../embeddings/embeddedObject*N*.bin:

```
<Relationships xmlns="…">
  <Relationship Id="rId6"
    Type="http://…/oleObject"
    Target="../embeddings/embeddedObject1.bin"/>
  <Relationship Id="rId7"
    Type="http://…/oleObject"
    Target="../embeddings/embeddedObject2.bin"/>
</Relationships>
```

end example]

An Embedded Object part may be located within or external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element may be `Internal` or `External`).

An Embedded Object part is permitted to have an explicit relationship to the following parts defined by this Standard:

- Hyperlink (§15.3)

An Embedded Object part shall not have any implicit or explicit relationships to other parts defined by this Standard.

15.2.10 Embedded Package Part

Content Type:	application/vnd.openxmlformats-officedocument.package
Root Namespace:	not applicable
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/package

An instance of this part type contains a complete package. For example, a WordprocessingML document might contain a SpreadsheetML or PresentationML document, in which case, the WordprocessingML document package would contain an embedded package part that defined that SpreadsheetML or PresentationML document.

A package is permitted to contain zero or more Embedded Package parts, and each such part shall be the target of an explicit relationship from a Chart (§14.2.1), Comments (§11.3.2), Endnotes (§11.3.4), Footer (§11.3.6), Footnotes (§11.3.7), Header (§11.3.9), or Main Document (§11.3.10) part in a WordprocessingML package; a Chart (§14.2.1), or Worksheet part (§12.3.24) in a SpreadsheetML package; or a Chart (§14.2.1),

Handout Master (§13.3.3), Notes Slide (§13.3.5), Notes Master (§13.3.4), Slide (§13.3.8), Slide Layout (§13.3.9), Slide Master (§13.3.10) part in a PresentationML package.

[*Example*: The following Presentation part-relationship item contains relationships to two Embedded Package parts: one is a SpreadsheetML package, which is stored in the ZIP item embeddings/Worksheet1.xlsx, the other is a PresentationML package, which is stored in the ZIP item embeddings/Presentation2.pptx. The image files are used as document display placeholders if the consumer cannot handle the embedded package type:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/image" Target="media/image1.emf"/>
  <Relationship Id="rId5"
    Type="http:package" Target="embeddings/Worksheet1.xlsx"/>
  <Relationship Id="rId6"
    Type="http://…/image" Target="media/image2.emf"/>
  <Relationship Id="rId7"
    Type="http://…/package" Target="embeddings/Presentation2.pptx"/>
</Relationships>
```

end example]

An Embedded Package part may be located within or external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element may be `Internal` or `External`).

An Embedded Package part is permitted to have an explicit relationship to the following parts defined by this Standard:

- Hyperlink (§15.3)

An Embedded Package part shall not have any implicit or explicit relationships to other parts defined by this Standard.

15.2.11 File Properties

There are three kinds of file properties: , *core*, *custom*, and *extended*. The *core file properties* of a package enable users to discover, get, and set common sets of properties from within that package, regardless of whether it's a WordprocessingML, SpreadsheetML, or PresentationML package. *Extended file properties* are specific to Office Open XML packages, while *custom file properties* are defined by the user, with each custom file property having a name, a value, and a type.

15.2.11.1 Core File Properties Part

Content Type:	application/vnd.openxmlformats-package.core-properties+xml
Root Namespace:	http://schemas.openxmlformats.org/package/2006/metadata/core-properties

Source Relationship:	http://schemas.openxmlformats.org/officedocument/2006/relationships/metadata/core-properties

Core file properties enable users to discover, get, and set common sets of properties within packages. (These properties include creator name, creation date, title, and description.) These properties are stored using the appropriate Dublin Core properties whenever possible.

A package shall contain at most one Core File Properties part, and that part shall be the target of a relationship in the package-relationship item for the document.

[*Example*: The following PresentationML's package-relationship item contains one relationship, for the Core File Properties part stored in the ZIP item core.xml):

```
<Relationships xmlns="…">
  <Relationship Id="rId3"
     Type="http://…/core-properties" Target="docProps/core.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be coreProperties.

[*Example*:

```
<cp:coreProperties xmlns:cp="…" xmlns:dc="…" >
  <dc:title>Example File</dc:title>
  <dc:creator>Tristan Davis</dc:creator>
  <cp:lastModifiedBy>Tristan Davis</cp:lastModifiedBy>
  <cp:revision>1</cp:revision>
</cp:coreProperties>
```

end example]

A Core File Properties part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Core File Properties part shall not have implicit or explicit relationships to other parts defined by this Standard.

15.2.11.2 Custom File Properties Part

Content Type:	application/vnd.openxmlformats-officedocument.custom-properties+xml
Root Namespace:	http://schemas.openxmlformats.org/officeDocument/2006/custom-properties

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/custom-properties

An instance of this part contains the names of custom file properties that apply to the package, their values, and the types of those values. A custom file property might be the name of the client for whom the document was prepared, a date/time on which some event happened, a document number, or some Boolean status flag.

A package shall contain at most one Custom File Properties part, and that part shall be the target of a relationship in the package-relationship item for the document.

[*Example*: The following PresentationML's package-relationship item contains a relationship to a Custom File Properties part, stored in the ZIP item docProps/custom.xml:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
  Type="http://…/custom-properties" Target="docProps/custom.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be Properties.

[*Example*: Here's some content markup from a WordprocessingML document, which contains four custom properties: `Client`, having a text value of "ACME Corp."; `Document number`, having a numeric value of 1543; `Recorded date`, having a date/time value of 2005-12-01; and `Special processing needed`, having a Boolean value of false:

```
<Properties … xmlns:vt="…">
  <property fmtid="{D5C…9AE}" pid="2" name="Client">
    <vt:lpwstr>ACME Corp.</vt:lpwstr>
  </property>
  <property fmtid="{D5C…9AE}" pid="3" name="Document number">
    <vt:i4>1543</vt:i4>
  </property>
  <property fmtid="{D5C…9AE}" pid="4" name="Recorded date">
    <vt:filetime>2005-12-01T05:00:00Z</vt:filetime>
  </property>
  <property fmtid="{D5C…9AE}" pid="5" name="Special processing needed">
    <vt:bool>false</vt:bool>
  </property>
</Properties>
```

end example]

A Custom File Properties part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Custom File Properties part shall not have implicit or explicit relationships to other parts defined by this Standard.

15.2.11.3 Extended File Properties Part

Content Type:	application/vnd.openxmlformats-officedocument.extended-properties+xml
Root Namespace:	http://schemas.openxmlformats.org/officeDocument/2006/extended-properties
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/extended-properties

An instance of this part contains properties specific to an Office Open XML document.[*Example*: A PresentationML document specifies the number of slides in this presentation when last saved by a producer. *end example*]

A package shall contain at most one Extended File Properties part, and that part shall be the target of a relationship in the package-relationship item for the document.

[*Example*:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/extended-properties" Target="docProps/app.xml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be Properties.

[*Example*: Here's some content markup from a WordprocessingML document:

```
<Properties …>
  <Template>Normal.dotm</Template>
  <TotalTime>0</TotalTime>
  <Pages>1</Pages>
  <Words>3</Words>
  <Characters>22</Characters>
```

```
    <Application>Sample Producer</Application>
    <DocSecurity>0</DocSecurity>
    <Lines>1</Lines>
    <Paragraphs>1</Paragraphs>
    …
    <AppVersion>12.0000</AppVersion>
  </Properties>
```

here's some content markup from a SpreadsheetML document:

```
  <Properties …>
    <Application>Sample Producer</Application>
    <HeadingPairs>
    …
    </HeadingPairs>
    <TitlesOfParts>
    …
    </TitlesOfParts>
    <Company>Consultant</Company>
    …
  </Properties>
```

and here's some content markup from a PresentationML document:

```
  <Properties …>
    <Template>ppt_template_sdwest05</Template>
    <TotalTime>3166</TotalTime>
    <Words>37</Words>
    <Application>Sample Producer</Application>
    <PresentationFormat>On-screen Show</PresentationFormat>
    <Paragraphs>15</Paragraphs>
    <Slides>2</Slides>
    <Notes>2</Notes>
    …
    <HeadingPairs>
    …
    </HeadingPairs>
    <TitlesOfParts>
    …
    </TitlesOfParts>
    …
  </Properties>
```

end example]

A Extended File Properties part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

An Extended File Properties part shall not have implicit or explicit relationships to any other part defined by this Standard.

15.2.12 Font Part

Content Type:	application/x-fontdata application/x-font-ttf
Root Namespace:	not applicable
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/font

An instance of this part type contains a given font embedded directly into the document. (This is useful when using custom fonts or fonts that are not widely distributed.)

Fonts stored in a Font part can be stored in one of two formats, identified by the associated content type:

- `application/x-fontdata` specifies that the font shall be stored as a bitmapped font (each glyph is stored as a raster image)
- `application/x-font-ttf` specifies that the font shall be stored in the TrueType or OpenType format

A package shall contain zero or more Font parts, and for each that exists, that part shall be the target of an explicit relationship in the Font Table (§11.3.5), or Presentation (§13.3.6) part.

A Font part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Font part shall not have implicit or explicit relationships to other parts defined by this Standard.

15.2.13 Image Part

Content Type:	Any supported image type. [*Note*: Some example content types are:

image/gif	http://www.w3.org/Graphics/GIF/spec-gif89a.txt
image/png	ISO/IEC 15948:2003 http://www.libpng.org/pub/png/spec/
image/tiff	http://partners.adobe.com/public/developer/tiff/index.html#spec
image/pict	http://developer.apple.com/documentation/mac/QuickDraw/QuickDraw-2.html
image/jpeg	http://www.w3.org/Graphics/JPEG/

end note.]

Root Namespace:	Not applicable
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/image

An image can be stored in a package as a ZIP item. Image ZIP items shall be identified by an image part relationship and the appropriate content type.

A package is permitted to contain zero or more Image parts, and each such part shall be the target of an explicit relationship from a Comments (§11.3.2), Endnotes (§11.3.4), Footer (§11.3.6), Footnotes (§11.3.7), Header (§11.3.9), or Main Document (§11.3.10) part in a WordprocessingML package; a VML Drawing (§15.2.17) part in a SpreadsheetML package; or a Handout Master (§13.3.3), Notes Slide (§13.3.5), Notes Master (§13.3.4), Slide (§13.3.8), Slide Layout (§13.3.9), Slide Master (§13.3.10), or a VML Drawing (§15.2.17) part in a PresentationML package.

[*Example*: The following PresentationML's package-relationship item contains one relationship, for the slide template jpeg image stored in the ZIP item ../media/image1.jpeg:

```
<Relationships xmlns="…">
  <Relationship Id="rId8"
    Type="http://…/image" Target="../media/image1.jpeg"/>
</Relationships>
```

end example]

An Image part may be located within or external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element may be `Internal` or `External`).

An Image part shall not have implicit or explicit relationships to other parts defined by this Standard.

15.2.14 Printer Settings Part

Content Type:	application/vnd.openxmlformats-officedocument.spreadsheetml.printerSettings (in SpreadsheetML documents) application/vnd.openxmlformats-officedocument.wordprocessingml.printerSettings (in WordprocessingML documents)
Root Namespace:	not applicable
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings

An instance of this part type contains information about the initialization and environment of a printer or a display device. The layout of this data structure is application-defined. [*Example*: An Office Open XML producer

on Windows might store the DEVMODE structure defined here: http://msdn.microsoft.com/library/default.asp?url=/library/en-us/gdi/prntspol_8nle.asp, while an application on the Mac OS might choose to store the print record defined here: http://developer.apple.com/documentation/Carbon/Reference/CarbonPrintingManager_Ref/Reference/reference.html. *end example*]

A SpreadsheetML package is permitted to contain at most one Printer Settings part per Chartsheet, Dialogsheet, or Worksheet part, and that part shall be the target of an implicit relationship from a Chartsheet (§12.3.2), Dialogsheet (§12.3.7), or Worksheet (§12.3.24) part. A WordprocessingML package is permitted to contain zero or more Printer Settings parts, one per sectPr element, each a target of an explicit relationship from a Main Document (§11.3.10) or Glossary Document (§11.3.8) part.

[*Example*: The following SpreadsheetML Worksheet part-relationship item contains a relationship to a Printer Settings part, which is stored in the ZIP item ../printerSettings/printerSettings1.bin:

```
<Relationships xmlns="…">
  <Relationship Id="rId4"
    Type="http://…/printerSettings"
    Target="../printerSettings/printerSettings1.bin"/>
</Relationships>
```

end example]

A Printer Settings part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Printer Settings part shall not have implicit or explicit relationships to any other part defined by this Standard.

15.2.15 Thumbnail Part

<table>
<tr><td>Content Type:</td><td>Any supported image type.

[Note: Some example content types are:
<table>
<tr><td>image/gif</td><td>http://www.w3.org/Graphics/GIF/spec-gif89a.txt</td></tr>
<tr><td>image/png</td><td>ISO/IEC 15948:2003 http://www.libpng.org/pub/png/spec/</td></tr>
<tr><td>image/tiff</td><td>http://partners.adobe.com/public/developer/tiff/index.html#spec</td></tr>
<tr><td>image/pict</td><td>http://developer.apple.com/documentation/mac/QuickDraw/QuickDraw-2.html</td></tr>
<tr><td>image/jpeg</td><td>http://www.w3.org/Graphics/JPEG/</td></tr>
</table>
end note.]</td></tr>
<tr><td>Root Namespace:</td><td>Not applicable</td></tr>
</table>

Source Relationship:	http://schemas.openxmlformats.org/package/2006/relationships/metadata/thumbnail

To help end-users identify parts of a package or the package as a whole, images, called *thumbnails*, may be stored in that package. Each thumbnail image is generated by the package producer and is stored in the package as a ZIP item.

Thumbnail ZIP items shall be identified by either a package-relationship item or a part-relationship item. Packages shall not contain more than one thumbnail relationship associated with the package as a whole, or more than one thumbnail relationship per package part.

[*Example*: The following PresentationML's package-relationship item contains one relationship, for the metafile image stored in the ZIP item thumbnail.wmf:

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/thumbnail" Target="docProps/thumbnail.wmf"/>
</Relationships>
```

end example]

A Thumbnail part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A Thumbnail part shall not have implicit or explicit relationships to other parts defined by this Standard.

15.2.16 Video Part

Content Type:	Any supported video type. [*Note*: Some example content types are: video/x-ms-asf — http://www.microsoft.com/windows/windowsmedia/forpros/format/asfspec.aspx video/avi — http://www.the-labs.com/Video/odmlff2-avidef.pdf video/mpg — ISO/IEC 13818 video/mpeg — ISO/IEC 13818 video/x-ms-wm — http://www.microsoft.com/windows/windowsmedia/forpros/format/asfspec.aspx video/quicktime — http://developer.apple.com/softwarelicensing/agreements/quicktime.html *end note*]
Root Namespace:	not applicable

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/video

An instance of this part type contains a video file.

A PresentationML package is permitted to contain zero or more Video parts, each of which shall be the target of an explicit relationship in a Handout Master (§13.3.3), Notes Slide (§13.3.5), Notes Master (§13.3.4), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part. A WordprocessingML package is permitted to contain zero or more Video parts, each of which shall be the target of an explicit relationship from a Comments (§11.3.2), Endnotes (§11.3.4), Footer (§11.3.6), Footnotes (§11.3.7), Header (§11.3.9), or Main Document (§11.3.10) part.

[*Example*: The following Slide part-relationship item contains a relationship to a Video part, which is stored as the file E:\Video demo.avi:

```
<Relationships xmlns="…">
  <Relationship Id="rId2"
    Type="http://…/video"
    Target="file:///E:\Video%20demo.avi" TargetMode="External"/>
</Relationships>
```

end example]

A Video part is not stored as XML; instead, it involves a relationship target that is a video clip.

A Video part may be located within or external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element may be `Internal` or `External`).

A Video part shall not have implicit or explicit relationships to other parts defined by this Standard.

15.2.17 VML Drawing Part

Content Type:	application/vnd.openxmlformats-officedocument.vmlDrawing
Root Namespace:	not applicable
Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/vmlDrawing

An instance of this part type contains markup in the Vector Markup Language (VML) syntax, which is used to provide an alternative image representation of objects stored in a SpreadsheetML or PresentationML document.

[*Note*: The VML format is a legacy format originally introduced with Office 2000 and is included and fully defined in this Standard for backwards compatibility reasons. The DrawingML format is a newer and richer

format created with the goal of eventually replacing any uses of VML in the Office Open XML formats. VML should be considered a deprecated format included in Office Open XML for legacy reasons only and new applications that need a file format for drawings are strongly encouraged to use preferentially DrawingML. *end note*]

A package is permitted to contain zero or more VML Drawing parts, each of which shall be the target of an explicit relationship in a Handout Master (§13.3.3), Notes Slide (§13.3.5), Notes Master (§13.3.4), Slide (§13.3.8), Slide Layout (§13.3.9), or Slide Master (§13.3.10) part in a PresentationML document; or a Worksheet part (§12.3.24) in a SpreadsheetML document.

[*Example*: The following SpreadsheetML's package-relationship item contains one relationship, for the VML Drawing part stored in the ZIP item ../drawings/drawing1.vml:

```
<Relationships xmlns="…">
  <Relationship Id="rId8"
    Type="http://…/vmlDrawing" Target="../drawings/drawing1.vml"/>
</Relationships>
```

end example]

The root element for a part of this content type shall be xml in the null namespace, encapsulating an arbitrary amount of VML markup as defined by this Standard.

[*Example*: Consider the following VML Drawing part:

```
<xml>
  <v:shape ...>
    ...
  </v:shape>
  ...
</xml>
```

end example]

A VML Drawing part shall be located within the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element shall be `Internal`).

A VML Drawing part is permitted to have explicit relationships to the following parts defined by this Standard:

- Image (§15.2.13)

A VML Drawing part shall not have implicit or explicit relationships to any other part defined by this Standard.

15.3 Hyperlinks

Source Relationship:	http://schemas.openxmlformats.org/officeDocument/2006/relationships/hyperlink

A hyperlink can be stored in a package as a relationship. Hyperlinks shall be identified by containing a target which specifies the destination of the given hyperlink.

[*Example*: The following WordprocessingML Footnote part's relationship part contains one relationship, for the hyperlink http://schemas.openxmlformats.org/wordprocessingml/:

```
<Relationships xmlns="…">
  <Relationship Id="rId1"
    Type="http://…/hyperlink"
    Target="http://schemas.openxmlformats.org/wordprocessingml/"
    TargetMode="External"/>
</Relationships>
```

end example]

A hyperlink target may be located within or external to the package containing the source relationship (expressed syntactically, the TargetMode attribute of the Relationship element may be `Internal` or `External`).

Annex B. Index

This annex is informative.

Office Open XML

Part 2: Open Packaging Conventions

December 2006

Table of Contents

Foreword

This multi-part Standard deals with Office Open XML Format-related technology, and consists of the following parts:

- Part 1: "Fundamentals"
- **Part 2: "Open Packaging Conventions" (this document)**
- Part 3: "Primer"
- Part 4: "Markup Language Reference"
- Part 5: "Markup Compatibility and Extensibility"

This part, Part 2, includes a number of annexes that refer to data files provided in electronic form only.

1. Scope

This Part (the *Open Packaging Conventions specification*) specifies a set of conventions that are used by Office Open XML documents to define the structure and functionality of a *package* in terms of a package model and a physical model.

The *package model* defines a package abstraction that holds a collection of *parts*. The parts are composed, processed, and persisted according to a set of rules. Parts can have relationships to other parts or external resources, and the package as a whole can have relationships to parts it contains or external resources. The package model specifies how the parts of a package are named and related. Parts have content types and are uniquely identified using the well-defined naming guidelines provided in this Open Packaging specification.

The *physical mapping* defines the mapping of the components of the package model to the features of a specific physical format, namely a ZIP archive.

This Open Packaging Conventions specification also describes certain features that might be supported in a package, including *core properties* for package metadata, a *thumbnail* for graphical representation of a package, and *digital signatures* of package contents.

Because this Standard will continue to evolve, packages are designed to accommodate extensions and support compatibility goals in a limited way. The versioning and extensibility mechanisms described in Part 5: "Markup Compatibility and Extensibility" support compatibility between software systems based on different versions of this Standard while allowing package creators to make use of new or proprietary features.

This Open Packaging Conventions specification specifies requirements for package implementers, producers, and consumers.

In all subsequent uses, the term "this specification" shall refer to the content of this Part.

2. Normative References

The following normative documents contain provisions, which, through reference in this text, constitute provisions of this Open Packaging specification. For dated references, subsequent amendments to, or revisions of, any of these publications do not apply. However, parties to agreements based on this Open Packaging specification are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. For undated references, the latest edition of the normative document referred to applies. Members of ISO and IEC maintain registers of currently valid International Standards.

ISO 8601, *Data elements and interchange formats — Information interchange — Representation of dates and times*.

ISO/IEC 9594-8 *Public-key and attribute certificate frameworks* (x.509 Certificate).

ISO/IEC 10646 (all parts), *Information technology — Universal Multiple-Octet Coded Character Set (UCS)*.

3. Definitions

For the purposes of this Open Packaging specification, the following definitions apply. Other terms are defined where they appear in italic type. Terms explicitly defined in this Open Packaging specification are not to be presumed to refer implicitly to similar terms defined elsewhere.

The terms *base URI* and *relative reference* are used in accordance with RFC 3986.

access style — The style in which local access or networked access is conducted. The access styles are as follows: streaming creation, streaming consumption, simultaneous creation and consumption, and direct access consumption.

behavior — External appearance or action.

behavior, implementation-defined — Unspecified behavior where each implementation shall document that behavior, thereby promoting predictability and reproducibility within any given implementation. (This term is sometimes called “application-specific behavior”.)

behavior, unspecified —Behavior where this Open Packaging specification imposes no requirements.

communication style — The style in which package contents are delivered by a producer or received by a consumer. Communication styles include: random access and sequential delivery.

consumer — A piece of software or a device that reads packages through a package implementer. A consumer is often designed to consume packages only for a specific physical package format.

content type — Describes the content stored in a part. Content types define a media type, a subtype, and an optional set of parameters, as defined in RFC 2616.

Content Types stream — A specially-named stream that defines mappings from part names to content types. The content types stream is not itself a part, and is not URI addressable.

device — A piece of hardware, such as a personal computer, printer, or scanner, that performs a single function or set of functions.

format consumer — A consumer that consumes packages conforming to a format designer's specification.

format designer — The author of a particular file format specification built on this Open Packaging Conventions specification.

format producer — A producer that produces packages conforming to a format designer's specification.

growth hint — A suggested number of bytes to reserve for a part to grow in-place.

interleaved ordering — The layout style of a physical package where parts are broken into pieces and "mixed-in" with pieces from other parts. When delivered, interleaved packages can help improve the performance of the consumer processing the package.

layout style — The style in which the collection of parts in a physical package is laid out: either simple ordering or interleaved ordering.

local access — The access architecture in which a pipe carries data directly from a producer to a consumer on a single device.

logical item name — An abstraction that allows package implementers to manipulate physical data items consistently regardless of whether those data items can be mapped to parts or not or whether the package is laid out with simple ordering or interleaved ordering.

networked access — The access architecture in which a consumer and the producer communicate over a protocol, such as across a process boundary, or between a server and a desktop computer.

pack URI — A URI scheme that allows URIs to be used as a uniform mechanism for addressing parts within a package. Pack URIs are used as Base URIs for resolving relative references among parts in a package.

package — A logical entity that holds a collection of parts.

package implementer — Software that implements the physical input-output operations to a package according to the requirements and recommendations of this Open Packaging specification. A package implementer is used by a producer or consumer to interact with a physical package. A package implementer may be either a stand-alone API or may be an integrated component of a producer, consumer application, or device.

package model — A package abstraction that holds a collection of parts.

package relationship — A relationship whose target is a part and whose source is the package as a whole. Package relationships are found in the package relationships part named "/_rels/.rels".

part — A stream of bytes with a MIME content type and associated common properties. Typically corresponds to a file [*Example*: on a file system *end example*], a stream [*Example*: in a compound file *end example*], or a resource [*Example*: in an HTTP URI *end example*].

part name — The path component of a pack URI. Part names are used to refer to a part in the context of a package, typically as part of a URI.

physical model — A description of the capabilities of a particular physical format.

physical package format — A specific file format, or other persistence or transport mechanism, that can represent all of the capabilities of a package.

piece — A portion of a part. Pieces of different parts may be interleaved together. The individual pieces are named using a unique mapping from the part name. Piece name grammar is not equivalent to the part name grammar. Pieces are not addressable in the package model.

pipe — A communication mechanism that carries data from the producer to the consumer.

producer — A piece of software or a device that writes packages through a package implementer. A producer is often designed to produce packages according to a particular physical package format specification.

random access — A style of communication between the producer and the consumer of the package. Random access allows the consumer to reference and obtain data from anywhere within a package.

relationship —The kind of connection between a source part and a target part in a package. Relationships make the connections between parts directly discoverable without looking at the content in the parts, and without altering the parts themselves. (See also Package Relationships.)

relationships part — A part containing an XML representation of relationships.

sequential delivery — A communication style in which all of the physical bits in the package are delivered in the order they appear in the package.

signature policy — A format-defined policy that specifies what configuration of parts and relationships shall or might be included in a signature for that format and what additional behaviors that producers and consumers of that format shall follow when applying or verifying signatures following that format's signature policy.

simple ordering — A defined ordering for laying out the parts in a package in which all the bits comprising each part are stored contiguously.

simultaneous creation and consumption — A style of access between a producer and a consumer in highly pipelined environments where streaming creation and streaming consumption occur simultaneously.

stream — A linearly ordered sequence of bytes.

streaming consumption — An access style in which parts of a physical package may be processed by a consumer before all of the bits of the package have been delivered through the pipe.

streaming creation — A production style in which a producer dynamically adds parts to a package after other parts have been added without modifying those parts.

thumbnail — A small image that is a graphical representation of a part or the package as a whole.

well-known part — A part with a well-known relationship, which enables the part to be found without knowing the location of other parts.

ZIP archive — A ZIP file as defined in the ZIP file format specification. A ZIP archive contains ZIP items.

ZIP item — A ZIP item is an atomic set of data in a ZIP archive that becomes a file when the archive is uncompressed. When a user unzips a ZIP based package, the user sees an organized set of files and folders.

4. Notational Conventions

4.1 Document Conventions

The following typographical conventions are used in this Standard:

1. The first occurrence of a new term is written in *italics*. [*Example*: … is considered *normative*. *end example*]
2. A term defined as a basic definition is written in **bold**. [*Example*: **behavior** — External … *end example*]
3. The name of an XML element is written using an Element style. [*Example*: The root element is document. *end example*]
4. The name of an XML element attribute is written using an Attribute style. [*Example*: … an id attribute. *end example*]
5. An XML element attribute value is written using a `constant-width` style. [*Example*: … value of `CommentReference`. *end example*]
6. An XML element type name is written using a Type style. [*Example*: … as values of the xsd:anyURI data type. *end example*]

4.2 Diagram Notes

In some cases, markup semantics are described using diagrams. The diagrams place the parent element on the left, with attributes and child elements to the right. The symbols are described below.

Symbol	Description
	Required element: This box represents an element that shall appear exactly once in markup when the parent element is included. The "+" and "–" symbols on the right of these boxes have no semantic meaning.
	Optional element: This box represents an element that shall appear zero or one times in markup when the parent element is included.
	Range indicator: These numbers indicate that the designated element or choice of elements can appear in markup any number of times within the range specified.
	Attribute group: This box indicates that the enclosed boxes are each attributes of the parent element. Solid-border boxes are required attributes; dashed-border boxes are optional attributes.

Symbol	Description
	Sequence symbol: The element boxes connected to this symbol shall appear in markup in the illustrated sequence only, from top to bottom.
	Choice symbol: Only one of the element boxes connected to this symbol shall appear in markup.
	Type indicator: The elements within the dashed box are of the complex type indicated.

5. Acronyms and Abbreviations

This clause is informative.

The following acronyms and abbreviations are used throughout this specification:

IEC — the International Electrotechnical Commission

ISO — the International Organization for Standardization

W3C — World Wide Web Consortium

End of informative text.

6. General Description

This Open Packaging specification is intended for use by implementers, academics, and application programmers. As such, it contains a considerable amount of explanatory material that, strictly speaking, is not necessary in a formal specification.

This Open Packaging specification is divided into the following subdivisions:

1. Front matter (clauses 1–7);
2. Overview (clause 8);
3. Main body (clauses 9-13);
4. Annexes

Examples are provided to illustrate possible forms of the constructions described. References are used to refer to related clauses. Notes are provided to give advice or guidance to implementers or programmers. Annexes provide additional information and summarize the information contained in this Open Packaging specification.

The following form the normative part of this Open Packaging specification:

- Introduction
- Clauses 1–4, 6, and 8–12
- Annex A–Annex D
- Annex F

The following form the informative part of this Open Packaging specification:

- Clauses 5 and 7
- Annex E
- Annex G–Annex J
- All notes
- All examples

Whole clauses and annexes that are informative are identified as such. Informative text that is contained within normative text is identified as either an example, or a note as specified in 4.1, “Document Conventions.”

7. Overview

This clause is informative.

This Open Packaging specification describes an abstract model and physical format conventions for the use of XML, Unicode, ZIP, and other openly available technologies and specifications to organize the content and resources of a document within a package. It is intended to support the content types and organization for various applications and is written for developers who are building systems that process package content.

In addition, this Open Packaging specification defines common services that can be included in a package, such as Core Properties and Digital Signatures.

A primary goal is to ensure the interoperability of independently created software and hardware systems that produce or consume package content and use common services. This Open Packaging specification defines the formal requirements that producers and consumers shall satisfy in order to achieve interoperability.

Various XML-based building blocks within a package make use of the conventions described in Part 5: “Markup Compatibility and Extensibility” to facilitate future enhancement and extension of XML markup. That part shall be explicitly cited by any markup specification that bases its versioning and extensibility strategy on Markup Compatibility elements and attributes.

End of informative text.

8. Package Model

A *package* is a logical entity that holds a collection of parts. The purpose of the package is to aggregate all of the pieces of a document (or other type of content) into a single object. [*Example*: A package holding a document with a picture might contain two parts: an XML markup part representing the document and another part representing the picture. *end example*] The package is also capable of storing relationships between parts.

The package provides a convenient way to distribute documents with all of their component pieces, such as images, fonts, and data. Although this Open Packaging specification defines a single-file package format, the package model allows for the future definition of other physical package representations. [*Example:* A package could be physically represented in a collection of loose files, in a database, or ephemerally in transit over a network connection. *end example*]

This Open Packaging specification also defines a URI scheme, the *pack URI*, that allows URIs to be used as a uniform mechanism for addressing parts within a package.

8.1 Parts

A *part* is a stream of bytes with the properties listed in Table 8–1. A *stream* is a linearly ordered sequence of bytes. Parts are analogous to a file in a file system or to a resource on an HTTP server.

Table 8–1. Part properties

Name	Description	Required/Optional
Name	The name of the part	Required. The package implementer shall require a part name. [M1.1]
Content Type	The type of content stored in the part	Required. The package implementer shall require a content type and the format designer shall specify the content type. [M1.2]
Growth Hint	A suggested number of bytes to reserve for the part to grow in-place	Optional. The package implementer might allow a growth hint to be provided by a producer. [O1.1]

8.1.1 Part Names

Each part has a name. *Part names* refer to parts within a package. [*Example:* The part name "/hello/world/doc.xml" contains three segments: "hello", "world", and "doc.xml". The first two segments in the sample represent levels in the logical hierarchy and serve to organize the parts of the package, whereas the

third contains actual content. Note that segments are not explicitly represented as folders in the package model, and no directory of folders exists in the package model. *end example*]

Part Name Syntax

The part name grammar is defined as follows:

```
part_name = 1*( "/" segment )
segment   = 1*( pchar )
```

`pchar` is defined in RFC 3986.

The part name grammar implies the following constraints. The package implementer shall neither create any part that violates these constraints nor retrieve any data from a package as a part if the purported part name violates these constraints.

- A part name shall not be empty. [M1.1]
- A part name shall not have empty segments. [M1.3]
- A part name shall start with a forward slash (“/”) character. [M1.4]
- A part name shall not have a forward slash as the last character. [M1.5]
- A segment shall not hold any characters other than pchar characters. [M1.6]

Part segments have the following additional constraints. The package implementer shall neither create any part with a part name comprised of a segment that violates these constraints nor retrieve any data from a package as a part if the purported part name contains a segment that violates these constraints.

- A segment shall not contain percent-encoded forward slash (“/”), or backward slash (“\”) characters. [M1.7]
- A segment shall not contain percent-encoded unreserved characters. [M1.8]
- A segment shall not end with a dot (“.”) character. [M1.9]
- A segment shall include at least one non-dot character. [M1.10]

[*Example:*

Example 8–1. A part name

```
/a/%D1%86.xml
/xml/item1.xml
```

Example 8–2. An invalid part name

```
//xml/.
```

end example]

8.1.1.1 Part Naming

A package implementer shall neither create nor recognize a part with a part name derived from another part name by appending segments to it. [M1.11] [*Example*: If a package contains a part named "/segment1/segment2/.../segment*n*", then other parts in that package shall not have names such as: "/segment1", "segment1/segment2", or "/segment1/segment2/.../segment*n*-1". *end example]*

8.1.1.2 Part Name Equivalence

Part name equivalence is determined by comparing part names as case-insensitive ASCII strings. Packages shall not contain equivalent part names and package implementers shall neither create nor recognize packages with equivalent part names. [M1.12]

8.1.2 Content Types

Every part has a *content type*, which identifies the type of content that is stored in the part. Content types define a media type, a subtype, and an optional set of parameters. Package implementers shall only create and only recognize parts with a content type; format designers shall specify a content type for each part included in the format. Content types for package parts shall fit the definition and syntax for media types as specified in RFC 2616, §3.7. [M1.13] This definition is as follows:

```
media-type = type "/" subtype *( ";" parameter )
```

where parameter is expressed as

```
attribute "=" value
```

The type, subtype, and parameter attribute names are case-insensitive. Parameter values may be case-sensitive, depending on the semantics of the parameter attribute name.

Content types shall not use linear white space either between the type and subtype or between an attribute and its value. Content types also shall not have leading or trailing white spaces. Package implementers shall create only such content types and shall require such content types when retrieving a part from a package; format designers shall specify only such content types for inclusion in the format. [M1.14]

The package implementer shall require a content type that does not include comments and the format designer shall specify such a content type. [M1.15]

Format designers might restrict the usage of parameters for content types. [O1.2]

Content types for package-specific parts are defined in Annex F, "Standard Namespaces and Content Types."

8.1.3 Growth Hint

Sometimes a part is modified after it is placed in a package. Depending on the nature of the modification, the part might need to grow. For some physical package formats, this could be an expensive operation and could damage an otherwise efficiently interleaved package. Ideally, the part should be allowed to grow in-place, moving as few bytes as possible.

To support these scenarios, a package implementer can associate a growth hint with a part. [O1.1] The *growth hint* identifies the number of bytes by which the producer predicts that the part will grow. In a mapping to a particular physical format, this information might be used to reserve space to allow the part to grow in-place. This number serves as a hint only. The package implementer might ignore the growth hint or adhere only loosely to it when specifying the physical mapping. [O1.3] If the package implementer specifies a growth hint, it is set when a part is created and the package implementer shall not change the growth hint after the part has been created. [M1.16]

8.1.4 XML Usage

All XML content of the parts defined in this Open Packaging specification shall conform to the following validation rules:

1. XML content shall be encoded using either UTF-8 or UTF-16. If any part includes an encoding declaration, as defined in §4.3.3 of the XML 1.0 specification, that declaration shall not name any encoding other than UTF-8 or UTF-16. Package implementers shall enforce this requirement upon creation and retrieval of the XML content. [M1.17]
2. The XML 1.0 specification allows for the usage of Document Type Definitions (DTDs), which enable Denial of Service attacks, typically through the use of an internal entity expansion technique. As mitigation for this potential threat, DTD declarations shall not be used in the XML markup defined in this Open Packaging specification. Package implementers shall enforce this requirement upon creation and retrieval of the XML content and shall treat the presence of DTD declarations as an error. [M1.18]
3. If the XML content contains the Markup Compatibility namespace, as described in Part 5: “Markup Compatibility and Extensibility”, it shall be processed by the package implementer to remove Markup Compatibility elements and attributes, ignorable namespace declarations, and ignored elements and attributes before applying subsequent validation rules. [M1.19]
4. XML content shall be valid against the corresponding XSD schema defined in this Open Packaging specification. In particular, the XML content shall not contain elements or attributes drawn from namespaces that are not explicitly defined in the corresponding XSD unless the XSD allows elements or attributes drawn from any namespace to be present in particular locations in the XML markup. Package implementers shall enforce this requirement upon creation and retrieval of the XML content. [M1.20]
5. XML content shall not contain elements or attributes drawn from “xml” or “xsi” namespaces unless they are explicitly defined in the XSD schema or by other means described in this Open Packaging specification. Package implementers shall enforce this requirement upon creation and retrieval of the XML content. [M1.21]

8.2 Part Addressing

Parts often contain references to other parts. [*Example*: A package might contain two parts: an XML markup file and an image. The markup file holds a reference to the image so that when the markup file is processed, the associated image can be identified and located. *end example*.*]*

8.2.1 Relative References

A relative reference is expressed so that the address of the referenced part is determined relative to the part containing the reference.

Relative references from a part are interpreted relative to the base URI of that part. By default, the base URI of a part is derived from the name of the part, as defined in §B.3.

If the format designer permits it, parts can contain Unicode strings representing references to other parts. If allowed by the format designer, format producers can create such parts and format consumers shall consume them. [O1.4] In particular, XML markup might contain Unicode strings referencing other parts as values of the xsd:anyURI data type. Format consumers shall convert these Unicode strings to URIs, as defined in Annex A, "Resolving Unicode Strings to Part Names," before resolving them relative to the base URI of the part containing the Unicode string. [M1.23]

Some types of content provide a way to override the default base URI by specifying a different base in the content. [*Example*: XML Base or HTML *end example]*. In the presence of one of these overrides, format consumers shall use the specified base URI instead of the default. [M1.24]

[*Example:*

Example 8–3. Part names and relative references

A package includes parts with the following names:

- /markup/page.xml
- /images/picture.jpg
- /images/other_picture.jpg

If /markup/page.xml contains a reference to ../images/picture.jpg, then this reference is interpreted as referring to the part name /images/picture.jpg.

end example]

8.2.2 Fragments

Sometimes it is useful to address a portion of or a specific point in a part. In URIs, a fragment identifier is used for this purpose. (See RFC 3986.)

[*Example*: In an XML part a fragment identifier might identify a portion of the XML content using an XPath expression. *end example]*

8.3 Relationships

Parts often contain references to other parts in the package and to resources outside of the package. In general, these references are represented inside the referring part in ways that are specific to the content type of the part, that is, in arbitrary markup or an application-specific encoding. This effectively hides the internal and

external links between parts from consumers that do not understand the content types of the parts containing such references.

The package introduces a higher-level mechanism to describe references from parts to other internal or external resources: relationships. *Relationships* represent the type of connection between a source part and a target resource. They make the connection directly discoverable without looking at the part contents, so they are independent of content-specific schemas and quick to resolve.

Relationships provide a second important function: relating parts without modifying their content. Sometimes relationships act as a label where the content type of the labeled part does not define a way to attach the given information. Some scenarios require information to be attached to an existing part without modifying that part, either because the part is encrypted and cannot be decrypted, or because it is digitally signed and changing it would invalidate the signature.

8.3.1 Relationships Part

Each set of relationships sharing a common source is represented by XML stored in a *Relationships part*. The Relationships part is URI-addressable and it can be opened, read, and deleted. The Relationships part shall not have relationships to any other part. Package implementers shall enforce this requirement upon the attempt to create such a relationship and shall treat any such relationship as invalid. [M1.25]

The content type of the Relationships part is defined in Annex F, “Standard Namespaces and Content Types".

8.3.2 Package Relationships

A relationship whose source is a package as a whole is known as a *package relationship*. Package relationships are used to identify the “starting” parts in a package for a given context. This method avoids relying on naming conventions for finding parts in a package.

8.3.3 Relationship Markup

Relationships are represented using Relationship elements nested in a single Relationships element. These elements are defined in the Relationships namespace, as specified in Annex F, “Standard Namespaces and Content Types". The schema for relationships is described in Annex D, "Schemas - XML Schema".

The package implementer shall require that every Relationship element has an Id attribute, the value of which is unique within the Relationships part, and that the Id type is xsd:ID, the value of which conforms to the naming restrictions for xsd:ID as described in the W3C Recommendation “XML Schema Part 2: Datatypes.” [M1.26]

The nature of a Relationship element is identified by the Type attribute. Relationship Type is defined in the same way that namespaces are defined for XML namespaces. By using types patterned after the Internet domain-name space, non-coordinating parties can safely create non-conflicting relationship types.

Relationship types can be compared to determine whether two Relationship elements are of the same type. This comparison is conducted in the same way as when comparing URIs that identify XML namespaces: the two URIs are treated as strings and considered identical if and only if the strings have the same sequence of characters. The comparison is case-sensitive and no escaping is done or undone.

The Target attribute of the Relationship element holds a URI that points to a target resource. Where the URI is expressed as a relative reference, it is resolved against the base URI of the Relationships source part. The xml:base attribute shall not be used to specify a base URI for relationship XML content.

8.3.3.1 Relationships Element

The structure of a Relationships element is shown in the following diagram:

diagram	annotation	The root element of the Relationships part.

8.3.3.2 Relationship Element

The structure of a Relationship element is shown in the following diagram:

diagram						
attributes	Name	Type	Use	Default	Fixed	Annotation
	TargetMode	ST_TargetMode	optional			The package implementer might allow a TargetMode to be provided by a producer. [O1.5] The TargetMode indicates whether or not the target describes a resource inside the package or outside the package. The valid values are “Internal” and “External”. The default value is Internal. When set to Internal, the Target attribute shall be a relative reference and that

						reference is interpreted relative to the “parent” part. For package relationships, the package implementer shall resolve relative references in the Target attribute against the pack URI that identifies the entire package resource. [M1.29] For more information, see Annex B, “Pack URI.” When set to External, the Target attribute may be a relative reference or a URI. If the Target attribute is a relative reference, then that reference is interpreted relative to the location of the package.
	Target	xsd:anyURI	required			The package implementer shall require the Target attribute to be a URI reference pointing to a target resource. The URI reference shall be a URI or a relative reference. [M1.28] Target attribute values are dependent on the TargetMode attribute value.
	Type	xsd:anyURI	required			The package implementer shall require the Type attribute to be a URI that defines the role of the relationship and the format designer shall specify such a Type. [M1.27]
	Id	xsd:ID	required			The package implementer shall require a valid XML identifier. [M1.26] The Id type is xsd:ID and it shall conform to the naming restrictions for xsd:ID as specified in the W3C Recommendation “XML Schema Part 2: Datatypes.” The value of the Id

						attribute shall be unique within the Relationships part.
annotation	Represents a single relationship.					

A format designer might allow fragment identifiers in the value of the Target attribute of the Relationship element. [O1.6] If a fragment identifier is allowed in the Target attribute of the Relationship element, a package implementer shall not resolve the URI to a scope less than an entire part. [M1.32]

8.3.4 Representing Relationships

Relationships are represented in XML in a Relationships part. Each part in the package that is the source of one or more relationships can have an associated Relationships part. This part holds the list of relationships for the source part. For more information on the Relationships namespace and relationship types, see Annex F, "Standard Namespaces and Content Types."

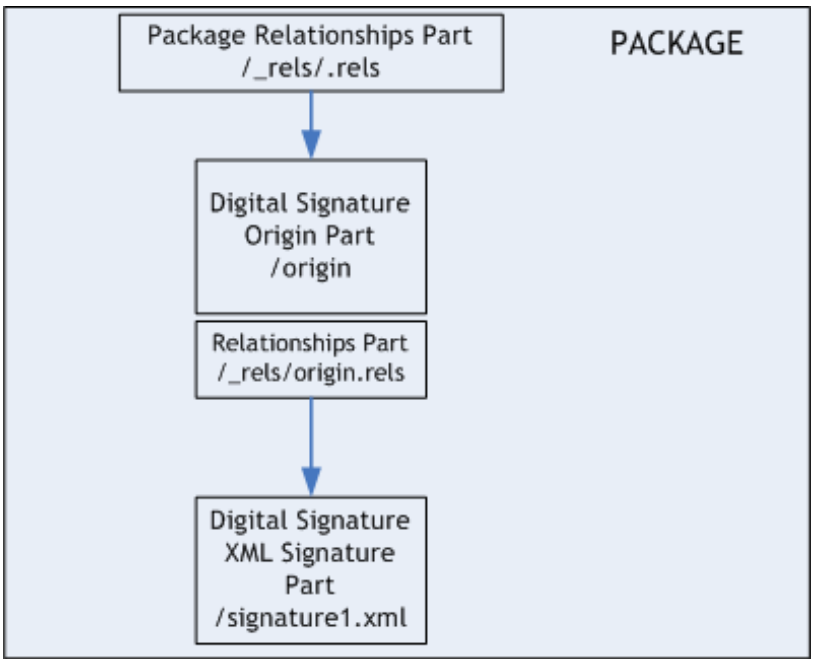
A special naming convention is used for the Relationships part. First, the Relationships part for a part in a given folder in the name hierarchy is stored in a sub-folder called "_rels". Second, the name of the Relationships part is formed by appending ".rels" to the name of the original part. Package relationships are found in the package relationships part named "/_rels/.rels".

The package implementer shall name relationship parts according to the special relationships part naming convention and require that parts with names that conform to this naming convention have the content type for a Relationships part. [M1.30]

[*Example:*

Example 8–4. Sample relationships and associated markup

The figure below shows a Digital Signature Origin part and a Digital Signature XML Signature part. The Digital Signature Origin part is targeted by a package relationship. The connection from the Digital Signature Origin to the Digital Signature XML Signature part is represented by a relationship.



The relationship targeting the Digital Signature Origin part is stored in /_rels/.rels and the relationship for the Digital Signature XML Signature part is stored in /_rels/origin.rels.

The Relationships part associated with the Digital Signature Origin contains a relationship that connects the Digital Signature Origin part to the Digital Signature XML Signature part. This relationship is expressed as follows:

```
<Relationships
   xmlns="http://schemas.openxmlformats.org/package/2006/relationships">
   <Relationship
      Target="./Signature.xml"
      Id="A5FFC797514BC"
      Type="http://schemas.openxmlformats.org/package/2006/relationships/
         digital-signature/signature"/>
</Relationships>
```

end example]

[*Example:*

Example 8–5. Targeting resources

Relationships can target resources outside of the package at an absolute location and resources located relative to the current location of the package. The following Relationships part specifies relationships that connect a part to pic1.jpg at an external absolute location, and to my_house.jpg at an external location relative to the location of the package:

```
<Relationships
   xmlns="http://schemas.openxmlformats.org/package/2006/relationships"
```

```
    <Relationship
       TargetMode="External"
       Id="A9EFC627517BC"
       Target="http://www.custom.com/images/pic1.jpg"
       Type="http://www.custom.com/external-resource"/>
    <Relationship
       TargetMode="External"
       Id="A5EFC797514BC"
       Target="./images/my_house.jpg"
       Type="http://www.custom.com/external-resource"/>
 </Relationships>
```

end example]

[*Example:*

Example 8–6. Re-using attribute values

The following Relationships part contains two relationships, each using unique Id values. The relationships share the same Target, but have different relationship types.

```
 <Relationships
    xmlns="http://schemas.openxmlformats.org/package/2006/relationships">
    <Relationship
       Target="./Signature.xml"
       Id="A5FFC797514BC"
       Type="http://schemas.openxmlformats.org/package/2006/
          relationships/digital-signature/signature"/>
    <Relationship
       Target="./Signature.xml"
       Id="B5F32797CC4B7"
       Type="http://www.custom.com/internal-resource"/>
 </Relationships>
```

end example]

8.3.5 Support for Versioning and Extensibility

Producers might generate relationship markup that uses the versioning and extensibility mechanisms defined in Part 5: “Markup Compatibility and Extensibility” to incorporate elements and attributes drawn from other XML namespaces. [O1.7]

Consumers shall process relationship markup in a manner that conforms to Part 5: “Markup Compatibility and Extensibility”. Producers editing relationships based on this version of the relationship markup specification shall not preserve any ignored content, regardless of the presence of any preservation attributes as defined in Part 5: “Markup Compatibility and Extensibility”. [M1.31]

9. Physical Package

In contrast to the package model that describes the contents of a package in an abstract way, the physical package refers to a package that is stored in a particular physical file format. This includes the physical model and physical mapping considerations.

The *physical model* abstractly describes the capabilities of a particular physical format and how producers and consumers can use a package implementer to interact with that physical package format. The physical model includes the *access style*, or the manner in which package input-output is conducted, as well as the *communication style*, which describes the method of interaction between producers and consumers across a communications *pipe*. The physical model also includes the *layout style*, or how part contents are physically stored within the package. The layout style can either be *simple ordering*, where the parts are arranged contiguously as atomic blocks of data, or *interleaved ordering*, where the parts are broken into individual pieces and the pieces are stored as interleaved blocks of data in an optimized fashion. The performance of a physical package design is reliant upon the physical model capabilities.

[*Note:* See Annex G, “Physical Model Design Considerations” for additional discussion of the physical model. *end note]*

Physical mappings describe the manner in which the package contents are mapped to the features of that specific physical format. Details of how package components are mapped are described, as well as common mapping patterns and mechanisms for storing part content types. This Open Packaging specification describes both the specific considerations for physical mapping to a ZIP archive as well as generic physical mapping considerations applicable to any physical package format.

9.1 Physical Mapping Guidelines

Whereas the package model defines a package abstraction, an *instance* of a package must be based on a physical representation. A *physical package format* is a particular physical representation of the package contents in a file.

Many physical package formats have features that partially match the packaging model components. In defining mappings from the package model to a physical package format, it is advisable to take advantage of any similarities in capabilities between the package model and the physical package medium while using layers of mapping to provide additional capabilities not inherently present in the physical package medium. [*Example*: Some physical package formats store parts as individual files in a file system, in which case it is advantageous to map many part names directly to identical physical file names. *end example]*

Designers of physical package formats face some common mapping problems. [*Example*: Associating arbitrary content types with parts and supporting part interleaving *end example]* Package implementers might use the common mapping solutions defined in this Open Packaging specification. [O2.3]

9.1.1 Mapped Components

The package implementer shall define a physical package format with a mapping for the required components package, part name, part content type and part contents. [M2.2] [*Note:* Not all physical package formats support the part growth hint. *end note*]

Table 9–1. Mapped components

Name	Description	Required/Optional
Package	URI-addressable resource that identifies package as a whole unit	Required. The package implementer shall provide a physical mapping for the package. [M2.2]
Part name	Names a part	Required. The package implementer shall provide a physical mapping for each part's name. [M2.2]
Part content type	Identifies the kind of content stored in the part	Required. The package implementer shall provide a physical mapping for each part's content type. [M2.2]
Part contents	Stores the actual content of the part	Required. The package implementer shall provide a physical mapping for each part's contents. [M2.2]
Part growth hint	Number of additional bytes to reserve for possible growth of part	Optional. The package implementer might provide a physical mapping for a growth hint that might be specified by a producer. [O2.2]

9.1.2 Mapping Content Types

Methods for mapping part content types to a physical format are described below.

9.1.2.1 Identifying the Part Content Type

The package implementer shall define a format mapping with a mechanism for associating content types with parts. [M2.3]

Some physical package formats have a native mechanism for representing content types. [*Example*: the content type header in MIME *end example]* For such packages, the package implementer should use the native mechanism to map the content type for a part. [S2.1]

For all other physical package formats, the package implementer should include a specially-named XML stream in the package called the *Content Types stream.* [S2.2] The Content Types stream shall not be mapped to a part by the package implementer. [M2.1] This stream is therefore not URI-addressable. However, it can be interleaved in the physical package using the same mechanisms used for interleaving parts.

9.1.2.2 Content Types Stream Markup

The Content Types stream identifies the content type for each package part. The Content Types stream contains XML with a top-level Types element, and one or more Default and Override child elements. Default elements define default mappings from the extensions of part names to content types. Override elements are used to specify content types on parts that are not covered by, or are not consistent with, the default mappings. Package producers can use pre-defined Default elements to reduce the number of Override elements on a part, but are not required to do so. [O2.4]

The package implementer shall require that the Content Types stream contain one of the following for every part in the package:

- One matching Default element
- One matching Override element
- Both a matching Default element and a matching Override element, in which case the Override element takes precedence. [M2.4]

The package implementer shall require that there not be more than one Default element for any given extension, and there not be more than one Override element for any given part name. [M2.5]

The order of Default and Override elements in the Content Types stream is not significant.

If the package is intended for streaming consumption:

- The package implementer should not allow Default elements; as a consequence, there should be one Override element for each part in the package.
- The format producer should write the Override elements to the package so they appear before the parts to which they correspond, or in close proximity to the part to which they correspond.

[S2.3]

The package implementer can define Default content type mappings even though no parts use them. [O2.5]

9.1.2.2.1 Types Element

The structure of a Types element is shown in the following diagram:

diagram	annotation	The root element of the Content Types stream.

9.1.2.2.2 Default Element

The structure of a Default element is shown in the following diagram:

diagram	
attributes

Name	Type	Use	Default	Fixed	Annotation
Extension	ST_Extension	required			A part name extension. A Default element matches any part whose name ends with a period followed by the value of this attribute. The package implementer shall require a non-empty extension in a Default element. [M2.6]
ContentType	ST_ContentType	required			A content type as defined in RFC 2616. Indicates the content type of any matching parts (unless overridden). The package implementer shall require a content type in a Default element and the format designer shall specify the content type. [M2.6]

annotation	Defines default mappings from the extensions of part names to content types.

9.1.2.2.3 Override Element

The structure of an Override element is shown in the following diagram:

diagram	
attributes	Name	Type	Use	Default	Fixed	Annotation
	ContentType	ST_ContentType	required			A content type as defined in RFC 2616. Indicates the content type of the matching part. The package implementer shall require a content type and the format designer shall specify the content type in an Override element. [M2.7]
	PartName	xs:anyURI	required			A part name. An Override element matches the part whose name is equal to the value of this attribute. The package implementer shall require a part name. [M2.7]
annotation	Specifies content types on parts that are not covered by, or are not consistent with, the default mappings.					

9.1.2.2.4 Content Types Stream Markup Example

[*Example:*

Example 9–7. Content Types stream markup

```
<Types
   xmlns="http://schemas.openxmlformats.org/package/2006/content-types">
   <Default Extension="txt" ContentType="text/plain" />
   <Default Extension="jpeg" ContentType="image/jpeg" />
   <Default Extension="picture" ContentType="image/gif" />
   <Override PartName="/a/b/sample4.picture" ContentType="image/jpeg" />
</Types>
```

The following is a sample list of parts and their corresponding content types as defined by the Content Types stream markup above.

Part name	Content type
/a/b/sample1.txt	text/plain
/a/b/sample2.jpg	image/jpeg
/a/b/sample3.picture	image/gif
/a/b/sample4.picture	image/jpeg

end example]

9.1.2.3 Setting the Content Type of a Part

When adding a new part to a package, the package implementer shall ensure that a content type for that part is specified in the Content Types stream; the package implementer shall perform the following steps to do so [M2.8]:

1. Get the extension from the part name by taking the substring to the right of the rightmost occurrence of the dot character (.) from the rightmost segment.
2. If a part name has no extension, a corresponding Override element shall be added to the Content Types stream.
3. Compare the resulting extension with the values specified for the Extension attributes of the Default elements in the Content Types stream. The comparison shall be case-insensitive ASCII.
4. If there is a Default element with a matching Extension attribute, then the content type of the new part shall be compared with the value of the ContentType attribute. The comparison might be case-sensitive and include every character regardless of the role it plays in the content-type grammar of RFC 2616, or it might follow the grammar of RFC 2616.

    a. If the content types match, no further action is required.
    b. If the content types do not match, a new Override element shall be added to the Content Types stream. .

5. If there is no Default element with a matching Extension attribute, a new Default element or Override element shall be added to the Content Types stream.

9.1.2.4 Getting the Content Type of a Part

To get the content type of a part, the package implementer shall perform the following steps [M2.9]:

1. Compare the part name with the values specified for the PartName attribute of the Override elements. The comparison shall be case-insensitive ASCII.
2. If there is an Override element with a matching PartName attribute, return the value of its ContentType attribute. No further action is required.
3. If there is no Override element with a matching PartName attribute, then

    a. Get the extension from the part name by taking the substring to the right of the rightmost occurrence of the dot character (.) from the rightmost segment.
    b. Check the Default elements of the Content Types stream, comparing the extension with the value of the Extension attribute. The comparison shall be case-insensitive ASCII.

4. If there is a Default element with a matching Extension attribute, return the value of its ContentType attribute. No further action is required.
5. If neither Override nor Default elements with matching attributes are found for the specified part name, the implementation shall not map this part name to a part.

9.1.2.5 Support for Versioning and Extensibility

The package implementer shall not use the versioning and extensibility mechanisms defined in Part 5: “Markup Compatibility and Extensibility” to incorporate elements and attributes drawn from other XML-namespaces into the Content Types stream markup. [M2.10]

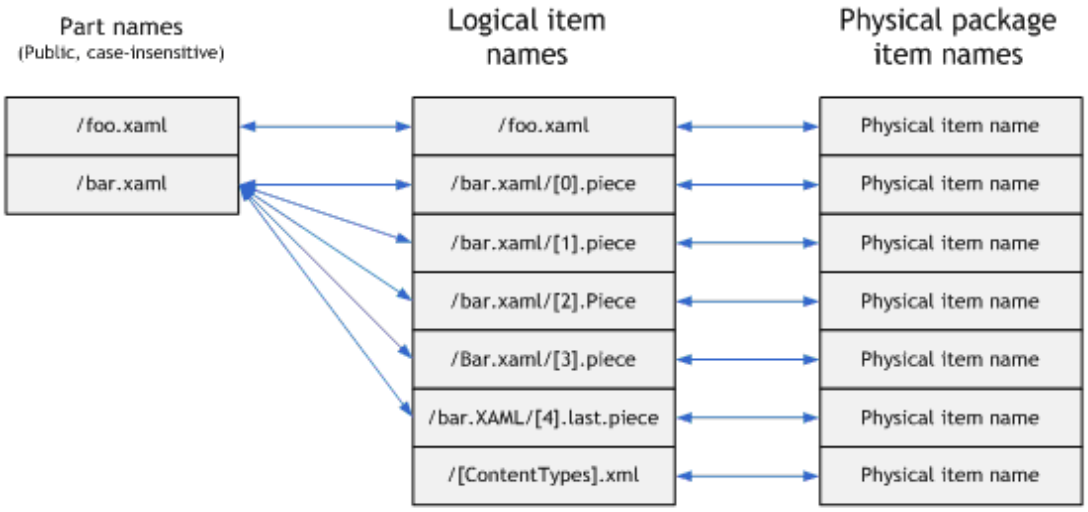
9.1.3 Mapping Part Names to Physical Package Item Names

The mapping of part names to the names of items in the physical package uses an intermediate *logical item name* abstraction. This logical item name abstraction allows package implementers to manipulate physical data items consistently regardless of whether those data items can be mapped to parts or not or whether the package is laid out with simple ordering or interleaved ordering. See §9.1.4 for interleaving details.

[*Example:*

Figure 9–1 illustrates the relationship between part names, logical item names, and physical package item names.

Figure 9–1. Part names and logical item names



end example]

9.1.3.1 Logical Item Names

Logical item names have the following syntax:

```
LogicalItemName = PrefixName [SuffixName]
PrefixName      = *AChar
AChar           = %x20-7E
SuffixName      = "/" "[" PieceNumber "]" [".last"] ".piece"
PieceNumber     = "0" | NonZeroDigit [1*Digit]
Digit           = "0" | NonZeroDigit
```

```
NonZeroDigit    = "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9"
```

[*Note:* Piece numbers identify the individual pieces of an interleaved part. *end note]*

The package implementer shall compare prefix names as case-insensitive ASCII strings. [M2.12]

The package implementer shall compare suffix names as case-insensitive ASCII strings. [M2.13]

Logical item names are considered equivalent if their prefix names and suffix names are equivalent. The package implementer shall not allow packages that contain equivalent logical item names. [M2.14] The package implementer shall not allow packages that contain logical items with equivalent prefix names and with equal piece numbers, where piece numbers are treated as integer decimal values. [M2.15]

Logical item names that use suffix names form a complete sequence if and only if:

1. The prefix names of all logical item names in the sequence are equivalent, and
2. The suffix names of the sequence start with “/[0].piece” and end with “/[n].last.piece” and include a piece for every piece number between 0 and n, without gaps, when the piece numbers are interpreted as decimal integer values.

9.1.3.2 Mapping Part Names to Logical Item Names

Non-interleaved part names are mapped to logical item names that have an equivalent prefix name and no suffix name.

Interleaved part names are mapped to the complete sequence of logical item names with an equivalent prefix name.

9.1.3.3 Mapping Logical Item Names and Physical Package Item Names

The mapping of logical item names and physical package item names is specific to the particular physical package.

9.1.3.4 Mapping Logical Item Names to Part Names

A logical item name without a suffix name is mapped to a part name with an equivalent prefix name provided that the prefix name conforms to the part name syntax.

A complete sequence of logical item names is mapped to the part name that is equal to the prefix name of the logical item name having the suffix name “/[0].piece”, provided that the prefix name conforms to the part name syntax.

The package implementer might allow a package that contains logical item names and complete sequences of logical item names that cannot be mapped to a part name because the logical item name does not follow the part naming grammar or the logical item does not have an associated content type. [O2.7] The package implementer shall not map logical items to parts if the logical item names violate the part naming rules. [M2.16]

The package implementer shall consider naming collisions within the set of part names mapped from logical item names to be an error. [M2.17]

9.1.4 Interleaving

Not all physical packages natively support interleaving of the data streams of parts. The package implementer should use the mechanism described in this Open Packaging specification to allow interleaving when mapping to the physical package for layout scenarios that support streaming consumption. [S2.4]

The interleaving mechanism breaks the data stream of a part into *pieces*, which can be interleaved with pieces of other parts or with whole parts. Pieces are named using a unique mapping from the part name, defined in §9.1.3. This enables a consumer to join the pieces together in their original order, forming the data stream of the part.

The individual pieces of an interleaved part exist only in the physical package and are not addressable in the packaging model. A piece might be empty.

An individual part shall be stored either in an interleaved or non-interleaved fashion. The package implementer shall not mix interleaving and non-interleaving for an individual part. [M2.11] The format designer specifies whether that format might use interleaving. [O2.1]

The grammar for deriving piece names from a given part name is defined by the logical item name grammar as defined in §9.1.3.1. A suffix name is mandatory.

The package implementer should store pieces in their natural order for optimal efficiency. [S2.5] The package implementer might create a physical package containing interleaved parts and non-interleaved parts. [O2.6]

[*Example:*

Example 9–8. ZIP archive contents

A ZIP archive might contain the following item names mapped to part pieces and whole parts:

```
spine.xml/[0].piece
pages/page0.xml
spine.xml/[1].piece
pages/page1.xml
spine.xml/[2].last.piece
pages/page2.xml
```

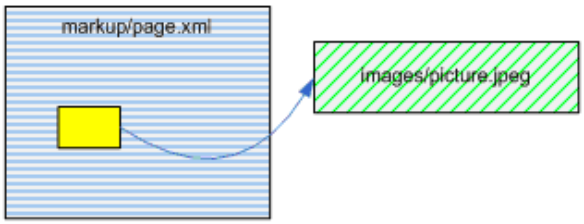
end example]

Under certain scenarios, interleaved ordering can provide important performance benefits, as demonstrated in the following example.

[*Example:*

Example 9–9. Performance benefits with interleaved ordering

The figure below contains two parts: a page part (markup/page.xml) describing the contents of a page, and an image part (images/picture.jpg) referring to an image that appears on the page.



With simple ordering, *all* of the bytes of the page part are delivered before the bytes of the image part. The figure below illustrates this scenario. The consumer is unable to display the image until it has received *all* of the page part *and* the image part. In some circumstances, such as small packages on a high-speed network, this may be acceptable. In others, having to read through all of markup/page.xml to get to the image results in unacceptable performance or places unreasonable memory demands on the consumer's system.

With interleaved ordering, performance is improved by splitting the page part into pieces and inserting the image part immediately following the reference to the image. This allows the consumer to begin processing the image as soon as it encounters the reference.

end example]

9.2 Mapping to a ZIP Archive

This Open Packaging specification defines a mapping for the ZIP archive format. Future versions of this Open Packaging specification might provide additional mappings.

A *ZIP archive* is a ZIP file as defined in the ZIP file format specification excluding all elements of that specification related to encryption, decryption, or digital signatures. A ZIP archive contains *ZIP items*. [*Note*: ZIP items become files when the archive is unzipped. When users unzip a ZIP-based package, they see a set of files and folders that reflects the parts in the package and their hierarchical naming structure. *end note*]

Table 9–2, Package model components and their physical representations, shows the various components of the package model and their corresponding physical representation in a ZIP archive.

Table 9–2. Package model components and their physical representations

Package model component	Physical representation
Package	ZIP archive file
Part	ZIP item
Part name	Stored in item header (and ZIP central directory as appropriate). See §9.2.3 for conversion rules.
Part content type	ZIP item containing XML that identifies the content types for each part according to the pattern described in §9.1.2.1.
Growth hint	Padding reserved in the ZIP Extra field in the local header that precedes the item. See §9.2.7 for a detailed description of the data structure.

9.2.1 Mapping Part Data

In a ZIP archive, the data associated with a part is represented as one or more items.

A package implementer shall store a non-interleaved part as a single ZIP item. [M3.1] When interleaved, a package implementer shall represent a part as one or more pieces, using the method described in §9.1.4. [M2.18] Pieces are named using the specified pattern, making it possible to rebuild the entire part from its constituent pieces. Each piece is stored within a ZIP archive as a single ZIP item.

In the ZIP archive, the chunk of bits that represents an item is stored contiguously. A package implementer might intentionally order the sequence of ZIP items in the archive to enable an efficient organization of the part data in order to achieve correct and optimal interleaving. [O3.1]

9.2.2 ZIP Item Names

ZIP item names are case-sensitive ASCII strings. Package implementers shall create ZIP item names that conform to ZIP archive file name grammar. [M3.2] Package implementers shall create item names that are unique within a given archive. [M3.3]

9.2.3 Mapping Part Names to ZIP Item Names

To map part names to ZIP item names the package implementer shall perform, in order, the following steps [M3.4]:

1. Convert the part name to a logical item name or, in the case of interleaved parts, to a complete sequence of logical item names.
2. Remove the leading forward slash (/) from the logical item name or, in the case of interleaved parts, from each of the logical item names within the complete sequence.

The package implementer shall not map a logical item name or complete sequence of logical item names sharing a common prefix to a part name if the logical item prefix has no corresponding content type. [M3.5]

9.2.4 Mapping ZIP Item Names to Part Names

To map ZIP item names to part names, the package implementer shall perform, in order, the following steps [M3.6]:

1. Map the ZIP item names to logical item names by adding a forward slash (/) to each of the ZIP item names.
2. Map the obtained logical item names to part names. For more information, see §9.1.3.4.

9.2.5 ZIP Package Limitations

The package implementer shall map all ZIP items to parts except MS-DOSZIP items, as defined in the ZIP specification, that are not MS-DOS files. [M3.7]

[*Note:* The ZIP specification specifies that ZIP items recognized as MS-DOS files are those with a "version made by" field and an "external file attributes" field in the "file header" record in the central directory that have a value of 0. *end note]*

In ZIP archives, the package implementer shall not exceed 65,535 bytes for the combined length of the item name, Extra field, and Comment fields. [M3.8] Accordingly, part names stored in ZIP archives are limited to 65,535 characters, subtracting the size of the Extra and Comment fields.

Package implementers should restrict part naming to accommodate file system limitations when naming parts to be stored as ZIP items. [S3.1]

[*Example:*

Examples of these limitations are:

- On Windows file systems, the asterisk ("*") and colon (":") are not valid, so parts named with this character will not unzip successfully.
- On Windows file systems, many programs can handle only file names that are less than 256 characters *including* the full path; parts with longer names might not behave properly once unzipped.
- On Unix file systems, the semicolon (";") has a special meaning, so parts with this character might not be processed as expected.

end example]

ZIP-based packages shall not include encryption as described in the ZIP specification. Package implementers shall enforce this restriction. [M3.9]

9.2.6 Mapping Part Content Type

Part content types are used for associating content types with part data within a package. In ZIP archives, content type information is stored using the common mapping pattern that stores this information in a single XML stream as follows:

- Package implementers shall store content type data in an item(s) mapped to the logical item name with the prefix_name equal to “/[Content_Types].xml” or in the interleaved case to the complete sequence of logical item names with that prefix_name. [M3.10]

Package implementers shall not map logical item name(s) mapped to the Content Types stream in a ZIP archive to a part name. [M3.11] [*Note*: Bracket characters "[" and "]" were chosen for the Content Types stream name specifically because these characters violate the part naming grammar, thus reinforcing this requirement. *end note*]

9.2.7 Mapping the Growth Hint

In a ZIP archive, the growth hint is used to reserve additional bytes that can be used to allow an item to grow in-place. The padding is stored in the Extra field, as defined in the ZIP file format specification. If a growth hint is used for an interleaved part, the package implementer should store the Extra field containing the growth hint padding with the item that represents the first piece of the part. [S3.2]

The format of the ZIP item's Extra field, when used for growth hints, is shown in Table 9–3, Structure of the Extra field for growth hints below.

Table 9–3. Structure of the Extra field for growth hints

Field	Size	Value
Header ID	2 bytes	A220
Length of Extra field	2 bytes	The signature length (2 bytes) + the padding initial value length (2 bytes) + Length of the padding (variable)
Signature (for verification)	2 bytes	A028
Padding Initial Value	2 bytes	Hex number value is set by the producer when the item is created
<padding>	[Padding Length]	Should be filled with NULL characters

9.2.8 Late Detection of ZIP Items Unfit for Streaming Consumption

Several substantial conditions that represent a package unfit for streaming consumption may be detected mid-processing by a streaming package implementer. These include:

- A duplicate ZIP item name is detected the moment the second ZIP item with that name is encountered. Duplicate ZIP item names are not allowed. [M3.3]

- In interleaved packages, an incomplete sequence of ZIP items is detected when the last ZIP item is received. Because one of the interleaved pieces is missing, the entire sequence of ZIP items cannot be mapped to a part and is therefore invalid. [M2.16]
- An inconsistency between the local ZIP item headers and the ZIP central directory file headers is detected at the end of package consumption, when the central directory is processed.
- A ZIP item that is not a file, according to the file attributes in the ZIP central directory, is detected at the end of package consumption, when the central directory is processed. Only a ZIP item that is a file shall be mapped to a part in a valid package.

When any of these conditions are detected, the streaming package implementer shall generate an error, regardless of any processing that has already taken place. Package implementers shall not generate a package containing any of these conditions when generating a package intended for streaming consumption. [M3.13]

9.2.9 ZIP Format Clarifications for Packages

The ZIP format includes a number of features that packages do not support. Some ZIP features are clarified in the package context. See Annex C, “ZIP Appnote.txt Clarifications,” for package-specific ZIP information.

10. Core Properties

Core properties enable users to get and set well-known and common sets of property metadata within packages. The core properties and the Standard that describes them are shown in Table 10–1, “Core properties”. The namespace for the properties in this table in the Open Packaging Conventions domain are defined in Annex F, “Standard Namespaces and Content Types.”

Core property elements are non-repeatable. They may be empty or omitted. The Core Properties Part may be omitted if no core properties are present.

Table 10–1. Core properties

Property	Domain	Description
category	Open Packaging Conventions	A categorization of the content of this package. [*Example*: Example values for this property might include: Resume, Letter, Financial Forecast, Proposal, Technical Presentation, and so on. This value might be used by an application's user interface to facilitate navigation of a large set of documents. *end example*]
contentStatus	Open Packaging Conventions	The status of the content. [*Example*: Values might include “Draft”, “Reviewed”, and “Final”. *end example]*
contentType	Open Packaging Conventions	The type of content represented, generally defined by a specific use and intended audience. [*Example*: Values might include “Whitepaper”, “Security Bulletin”, and “Exam”. *end example]* [*Note*: This property is distinct from MIME content types as defined in RFC 2616. *end note]*
created	Dublin Core	Date of creation of the resource.
creator	Dublin Core	An entity primarily responsible for making the content of the resource.
description	Dublin Core	An explanation of the content of the resource. [*Example*: Values might include an abstract, table of contents, reference to a graphical representation of content, and a free-text account of the content. *end example]*
identifier	Dublin Core	An unambiguous reference to the resource within a given context.

Property	Domain	Description
keywords	Open Packaging Conventions	A delimited set of keywords to support searching and indexing. This is typically a list of terms that are not available elsewhere in the properties.
language	Dublin Core	The language of the intellectual content of the resource. [*Note*: IETF RFC 3066 provides guidance on encoding to represent languages. *end note*]
lastModifiedBy	Open Packaging Conventions	The user who performed the last modification. The identification is environment-specific. [*Example*: A name, email address, or employee ID. *end example]* It is recommended that this value be as concise as possible.
lastPrinted	Open Packaging Conventions	The date and time of the last printing.
modified	Dublin Core	Date on which the resource was changed.
revision	Open Packaging Conventions	The revision number. [*Example:* This value might indicate the number of saves or revisions, provided the application updates it after each revision. *end example]*
subject	Dublin Core	The topic of the content of the resource.
title	Dublin Core	The name given to the resource.
version	Open Packaging Conventions	The version number. This value is set by the user or by the application.

10.1 Core Properties Part

Core properties are stored in XML in the Core Properties part. The Core Properties part content type is defined in Annex F, “Standard Namespaces and Content Types.”

The structure of the CoreProperties element is shown in the following diagram:

diagram	annotation	Producers might provide all or a subset of these metadata properties to describe the contents of a package.

[*Example:*

Example 10–1. Core properties markup

An example of a core properties part is illustrated by this example:

```
<coreProperties
   xmlns="http://schemas.openxmlformats.org/package/2006/metadata/
      core-properties"
   xmlns:dcterms="http://purl.org/dc/terms/"
   xmlns:dc="http://purl.org/dc/elements/1.1/"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
   <dc:creator>Alan Shen</dc:creator>
   <dcterms:created xsi:type="dcterms:W3CDTF">
      2005-06-12
   </dcterms:created>
   <contentType>Functional Specification</contentType>
   <dc:title>OPC Core Properties</dc:title>
```

```
    <dc:subject>Spec defines the schema for OPC Core Properties and their
       location within the package</dc:subject>
    <dc:language>eng</dc:language>
    <version>1.0</version>
    <lastModifiedBy>Alan Shen</lastModifiedBy>
    <dcterms:modified xsi:type="dcterms:W3CDTF">2005-11-23</dcterms:modified>
    <contentStatus>Reviewed</contentStatus>
    <category>Specification</category>
  </coreProperties>
```

end example]

10.2 Location of Core Properties Part

The location of the Core Properties part within the package is determined by traversing a well-defined package relationship as listed in Annex F, “Standard Namespaces and Content Types”. The format designer shall specify and the format producer shall create at most one core properties relationship for a package. A format consumer shall consider more than one core properties relationship for a package to be an error. If present, the relationship shall target the Core Properties part. [M4.1]

10.3 Support for Versioning and Extensibility

The format designer shall not specify and the format producer shall not create Core Properties that use the Markup Compatibility namespace as defined in Annex F, “Standard Namespaces and Content Types”. A format consumer shall consider the use of the Markup Compatibility namespace to be an error. [M4.2] Instead, versioning and extensibility functionality is accomplished by creating a new part and using a relationship with a new type to point from the Core Properties part to the new part. This Open Packaging specification does not provide any requirements or guidelines for new parts or relationship types that are used to extend core properties.

10.4 Schema Restrictions for Core Properties

The following restrictions apply to every XML document instance that contains Open Packaging Conventions core properties:

1. Producers shall not create a document element that contains refinements to the Dublin Core elements, except for the two specified in the schema: <dcterms:created> and <dcterms:modified> Consumers shall consider a document element that violates this constraint to be an error. [M4.3]
2. Producers shall not create a document element that contains the xml:lang attribute. Consumers shall consider a document element that violates this constraint to be an error. [M4.4] For Dublin Core elements, this restriction is enforced by applications.
3. Producers shall not create a document element that contains the xsi:type attribute, except for a <dcterms:created> or <dcterms:modified> element where the xsi:type attribute shall be present and shall hold the value dcterms:W3CDTF, where `dcterms` is the namespace prefix of the Dublin Core

namespace. Consumers shall consider a document element that violates this constraint to be an error. [M4.5]

11. Thumbnails

The format designer might allow images, called *thumbnails*, to be used to help end-users identify parts of a package or a package as a whole. These images can be generated by the producer and stored as parts. [O5.1]

11.1 Thumbnail Parts

The format designer shall specify thumbnail parts that are identified by either a part relationship or a package relationship. The producer shall build the package accordingly. [M5.1] For information about the relationship type for Thumbnail parts, see Annex F, “Standard Namespaces and Content Types.”

12. Digital Signatures

Format designers might allow a package to include digital signatures to enable consumers to validate the integrity of the contents. The producer might include the digital signature when allowed by the format designer. [O6.1] Consumers can identify the parts of a package that have been signed and the process for validating the signatures. Digital signatures do not protect data from being changed. However, consumers can detect whether signed data has been altered and notify the end-user, restrict the display of altered content, or take other actions.

Producers incorporate digital signatures using a specified configuration of parts and relationships. This clause describes how the package digital signature framework applies the W3C Recommendation "XML-Signature Syntax and Processing" (referred to here as the "XML Digital Signature specification"). In addition to complying with the XML Digital Signature specification, producers and consumers also apply the modifications specified in §12.2.4.1.

12.1 Choosing Content to Sign

Any part or relationship in a package can be signed, including Digital Signature XML Signature parts themselves. An entire Relationships part or a subset of relationships can be signed. By signing a subset, other relationships can be added, removed, or modified without invalidating the signature.

Because applications use the package format to store various types of content, application designers that include digital signatures should define signature policies that are meaningful to their users. A signature policy specifies which portions of a package should not change in order for the content to be considered intact. To ensure validity, some clients require that *all* of the parts and relationships in a package be signed. Others require that *selected* parts or relationships be signed and validated to indicate that the content has not changed. The digital signature infrastructure in packages provides flexibility in defining the content to be signed, while allowing parts of the package to remain changeable.

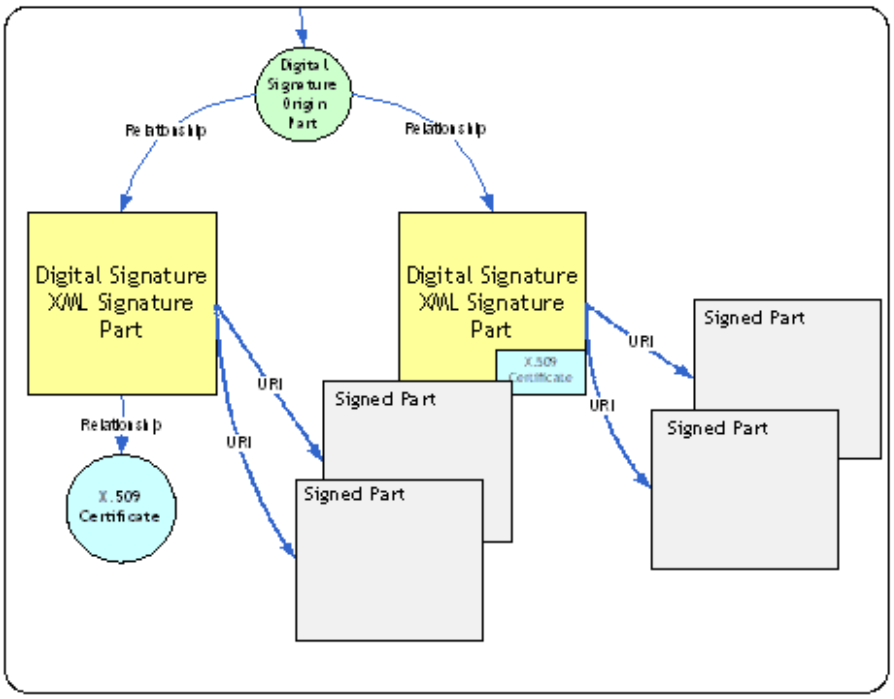
12.2 Digital Signature Parts

The digital signature parts consist of the Digital Signature Origin part, Digital Signature XML Signature parts, and Digital Signature Certificate parts. Relationship names and content types relating to the use of digital signatures in packages are defined in Annex F, "Standard Namespaces and Content Types."

[*Example:*

Figure 12–1 shows a signed package with signature parts, signed parts, and an X.509 certificate. The example Digital Signature Origin part references two Digital Signature XML Signature parts, each containing a signature. The signatures relate to the signed parts.

Figure 12–1. A signed package



end example]

12.2.1 Digital Signature Origin Part

The Digital Signature Origin part is the starting point for navigating through the signatures in a package. The package implementer shall include only one Digital Signature Origin part in a package and it shall be targeted from the package root using the well-defined relationship type specified in Annex F, “Standard Namespaces and Content Types”. [M6.1] When creating the first Digital Signature XML Signature part, the package implementer shall create the Digital Signature Origin part, if it does not exist, in order to specify a relationship to that Digital Signature XML Signature part. [M6.2] If there are no Digital Signature XML Signature parts in the package, the Digital Signature Origin part is optional. [O6.2] Relationships to the Digital Signature XML Signature parts are defined in the Relationships part. The producer should not create any content in the Digital Signature Origin part itself. [S6.1]

The producer shall create Digital Signature XML Signature parts that have a relationship from the Digital Signature Origin part and the consumer shall use that relationship to locate signature information within the package. [M6.3]

12.2.2 Digital Signature XML Signature Part

Digital Signature XML Signature parts are targeted from the Digital Signature Origin part by a relationship that uses the well-defined relationship type specified in Annex F, “Standard Namespaces and Content Types”. The Digital Signature XML Signature part contains digital signature markup. The producer might create zero or more Digital Signature XML Signature parts in a package. [O6.4]

12.2.3 Digital Signature Certificate Part

If present, the Digital Signature Certificate part contains an X.509 certificate for validating the signature. Alternatively, the producer might store the certificate as a separate part in the package, might embed it within the Digital Signature XML Signature part itself, or might not include it in the package if certificate data is known or can be obtained from a local or remote certificate store. [O6.5]

The package digital signature infrastructure supports X.509 certificate technology for signer authentication.

If the certificate is represented as a separate part within the package, the producer shall target that certificate from the appropriate Digital Signature XML Signature part by a Digital Signature Certificate relationship as specified in Annex F, "Standard Namespaces and Content Types" and the consumer shall use that relationship to locate the certificate. [M6.4] The producer might sign the part holding the certificate. [O6.6] The content types of the Digital Signature Certificate part and the relationship targeting it from the Digital Signature XML Signature part are defined in Annex F, "Standard Namespaces and Content Types", Producers might share Digital Signature Certificate parts by using the same certificate to create more than one signature. [O6.7] Producers generating digital signatures should not create Digital Signature Certificate parts that are not the target of at least one Digital Signature Certificate relationship from a Digital Signature XML Signature part. In addition, producers should remove a Digital Signature Certificate part if removing the last Digital Signature XML Signature part that has a Digital Signature Certificate relationship to it. [S6.2]

12.2.4 Digital Signature Markup

The markup described here includes a subset of elements and attributes from the XML Digital Signature specification and some package-specific markup. For a complete example of a digital signature, see §12.3.

12.2.4.1 Modifications to the XML Digital Signature Specification

The package modifications to the XML Digital Signature specification are summarized as follows:

1. The producer shall create Reference elements within a SignedInfo element that reference elements within the same Signature element. The consumer shall consider Reference elements within a SignedInfo element that reference any resources outside the same Signature element to be in error. [M6.5] The producer should only create Reference elements within a SignedInfo element that reference an Object element. [S6.5] The producer shall not create a reference to a package-specific Object element that contains a transform other than a canonicalization transform. The consumer shall consider a reference to a package-specific Object element that contains a transform other than a canonical transform to be an error. [M6.6]
2. The producer shall create one and only one package-specific Object element in the Signature element. The consumer shall consider zero or more than one package-specific Object element in the Signature element to be an error. [M6.7]

The producer shall create package-specific Object elements that contain exactly one Manifest element and exactly one SignatureProperties element. [*Note:* This SignatureProperties element can contain multiple SignatureProperty elements. *end note*] The consumer shall consider package-specific Object elements that

contain other types of elements to be an error. [M6.8] [*Note:* A signature may contain other Object elements that are not package-specific. *end note]*

a. The producer shall create Reference elements within a Manifest element that reference with their URI attribute only parts within the package. The consumer shall consider Reference elements within a Manifest element that reference resources outside the package to be an error. [M6.9] The producer shall create relative references to the local parts that have query components that specifies the part content type as described in §12.2.4.6. The relative reference excluding the query component shall conform to the part name grammar. The consumer shall consider a relative reference to a local part that has a query component that incorrectly specifies the part content type to be an error. [M6.10] The producer shall create Reference elements with a query component that specifies the content type that matches the content type of the referenced part. The consumer shall consider signature validation to fail if the part content type compared in a case-sensitive manner to the content type specified in the query component of the part reference does not match. [M6.11]
b. The producer shall not create Reference elements within a Manifest element that contain transforms other than the canonicalization transform and relationships transform. The consumer shall consider Reference elements within a Manifest element that contain transforms other than the canonicalization transform and relationships transform to be in error. [M6.12]
c. A producer that uses an optional relationships transform shall follow it by a canonicalization transform. The consumer shall consider any relationships transform that is not followed by a canonicalization transform to be an error. [M6.13]
d. The producer shall create exactly one SignatureProperty element with the Id attribute value set to `idSignatureTime`. The Target attribute value of this element shall be either empty or contain a fragment reference to the value of the Id attribute of the root Signature element. A SignatureProperty element shall contain exactly one SignatureTime child element. The consumer shall consider a SignatureProperty element that does not contain a SignatureTime element or whose Target attribute value is not empty or does not contain a fragment reference the Id attribute of the ancestor Signature element to be in error. [M6.14].

[*Note*: All modifications to XML Digital Signature markup occur in locations where the XML Signature schema allows any namespace. Therefore, package digital signature XML is valid against the XML Signature schema. *end note]*

12.2.4.2 Signature Element

The structure of a Signature element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
attributes	Name: Id; Type: xs:ID; Use: optional; Default: ; Fixed: ; Annotation: A unique identifier of the signature xml document.
annotation	The root element of the signature xml document stored in a signature part. The producer shall create a Signature element that contains exactly one local-data, package-specific Object element and zero or more application-specific Object elements. If a Signature element violates this constraint, a consumer shall consider this to be an error. [M6.15]

12.2.4.3 SignedInfo Element

The structure of a SignedInfo element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
annotation	Specifies the data in the package that is signed. Holds one or more references to Object elements within the same Digital Signature XML Signature part. The producer shall create a SignedInfo element that contains exactly one reference to the package-specific Object element. The consumer shall consider it an error if a SignedInfo element does not contain a reference to the package-specific Object element. [M6.16]

12.2.4.4 CanonicalizationMethod Element

The structure of a CanonicalizationMethod element is shown in the following diagram:

diagram	
namespace	http://www.w3.org/2000/09/xmldsig#
attributes	Name: Algorithm; Type: xs:anyURI; Use: required; Default: ; Fixed: ; Annotation: Contains a URI that identifies the particular canonicalization algorithm.
annotation	Specifies the canonicalization algorithm applied to the SignedInfo element prior to performing signature calculations.

Since XML allows equivalent content to be represented differently, a producer should apply a canonicalization transform to the SignedInfo element when it generates it, and a consumer should apply the canonicalization transform to the SignedInfo element when validating it. [S6.3]

[*Note*: Performing a canonicalization transform ensures that SignedInfo content can be validated even if the content has been regenerated using, for example, different entity structures, attribute ordering, or character encoding.

Producers and consumers should also use canonicalization transforms for references to parts that hold XML documents. These transforms are defined using the Transformelement. *end note]*

The following canonicalization methods shall be supported by producers and consumers of packages with digital signatures:

- XML Canonicalization (c14n)
- XML Canonicalization with Comments (c14n with comments)

Consumers validating signed packages shall fail the validation if other canonicalization methods are encountered. [M6.34]

12.2.4.5 SignatureMethod Element

The structure of a SignatureMethod element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
attributes	Name: Algorithm; Type: xs:anyURI; Use: required; Default: ; Fixed: ; Annotation: Contains a URI that identifies the particular algorithm for the signature method.
annotation	Defines the algorithm that is used to convert the SignedInfo element into a hashed value contained in the SignatureValueelement. Producers shall support DSA and RSA algorithms to produce signatures. Consumers shall support DSA and RSA algorithms to validate signatures. [M6.17]

12.2.4.6 Reference Element

The structure of a Reference element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
attributes	Name: URI; Type: xs:anyURI; Use: required; Default: ; Fixed: ; Annotation: Within a <SignedInfo> element, this attribute contains a URI that identifies an element within the signature xml document. Within a <Manifest> element, this attribute contains a relative reference composed of a reference to a part that conforms to the part name grammar and a query component that identifies the content type of

	that part.
annotation	Specifies the object being signed, a digest algorithm, a digest value, and a list of transforms to be applied prior to digesting.

12.2.4.6.1 Usage of <Reference> Element as <Manifest> Child Element

The producer shall create a Reference element within a Manifest element with a URI attribute and that attribute shall contain a part name, without a fragment identifier. The consumer shall consider a Reference element with a URI attribute that does not contain a part name to be an error. [M6.18]

References to package parts include the part content type as a query component. The syntax of the relative reference is as follows:

```
/page1.xml?ContentType="value"
```

where value is the content type of the targeted part.

[*Note:* See §12.2.4.1 for additional requirements on Reference elements. *end note]*

[*Example:*

Example 12–2. Part reference with query component

In the following example, the content type is “application/vnd.ms-package.relationships+xml”.

```
URI="/_rels/document.xml.rels?ContentType=application/vnd.ms-
package.relationships+xml"
```

end example]

12.2.4.7 Transforms Element

The structure of a Transforms element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
annotation	Contains an ordered list of Transform elements that describe how the producer digested the Object data before signing it.

The following transforms shall be supported by producers and consumers of packages with digital signatures:

- XML Canonicalization (c14n)
- XML Canonicalization with Comments (c14n with comments)
- Relationships transform (package-specific)

Consumers validating signed packages shall fail the validation if other transforms are encountered. Relationships transforms shall only be supported by producers and consumers when the Transform element is a descendant element of a Manifest element [M6.19]

12.2.4.8 Transform Element

The structure of a Transform element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
attributes	Name: Algorithm; Type: xs:anyURI; Use: required; Default: ; Fixed: ; Annotation: Contains a URI that identifies the particular transformation algorithm.
annotation	Describes how the signer obtained the Object data that was digested.

12.2.4.9 DigestMethod Element

The structure of a DigestMethod element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
attributes	Name; Type; Use; Default; Fixed; Annotation

	Algorithm	xs:anyURI	required			Contains a URI that identifies the particular digest method.
annotation	Defines the algorithm that yields the DigestValue from the object data after transforms are applied. Package producers and consumers shall support RSA-SHA1 algorithms to produce or validate signatures. [M6.17]					

12.2.4.10 DigestValue Element

The structure of a DigestValue element is shown in the following diagram:

diagram	
namespace	http://www.w3.org/2000/09/xmldsig#
annotation	Contains the encoded value of the digest in base64.

12.2.4.11 SignatureValue Element

The structure of a SignatureValue element is shown in the following diagram:

diagram						
namespace	http://www.w3.org/2000/09/xmldsig#					
attributes	Name	Type	Use	Default	Fixed	Annotation
	Id	xs:ID	optional			Contains a URI that identifies the SignatureValueelement within the signature xml document.
annotation	Contains the actual value of the digital signature in base64.					

12.2.4.12 Object Element

The Object element can be either package-specific or application-specific.

12.2.4.13 Package-Specific Object Element

The structure of a Object element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
attributes	Name: Id; Type: xs:ID; Use: ; Default: ; Fixed: ; Annotation: Shall have value of "idPackageObject".
annotation	Holds the Manifest and SignatureProperties elements that are package-specific.

[*Note:* Although the diagram above shows use of the Id attribute as optional, as does the XML Digital Signature schema, for package-specific Object elements, the Id attribute shall be specified and have the value of "idPackageObject". This is a package-specific restriction over and above the XML Digital Signature schema. *end note]*

The producer shall create each Signature element with exactly one package-specific Object. For a signed package, consumers shall treat the absence of a package-specific Object, or the presence of multiple package-specific Object elements, as an invalid signature. [M6.15]

12.2.4.14 Application-Specific Object Element

The application-specific Object element specifies application-specific information. The format designer might permit one or more application-specific Object elements. If allowed by the format designer, format producers can create one or more application-specific Object elements. [O6.8] Producers shall create application-specific Object elements that contain XML-compliant data; consumers shall treat data that is not XML-compliant as an error. [M6.20] Format designers and producers might not apply package-specific restrictions regarding URIs and Transform elements to application-specific Object element. [O6.9]

12.2.4.15 KeyInfo Element

The structure of a KeyInfo element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
annotation	Enables recipients to obtain the key needed to validate the signature. Can contain keys, names, certificates, and other public key management information. Producers and consumers shall use the certificate embedded in the Digital Signature XML Signature part when it is specified. [M6.21]

12.2.4.16 X509Data Element

The structure of an X509Data element is shown in the following diagram:

diagram	
namespace	http://www.w3.org/2000/09/xmldsig#
annotation	Contains one or more identifiers of X509 certificates.

12.2.4.17 X509Certificate Element

The structure of an X509Certificate element is shown in the following diagram:

diagram	
namespace	http://www.w3.org/2000/09/xmldsig#
annotation	Contains a base64-encoded X509 certificate.

12.2.4.18 Manifest Element

The structure of a Manifest element is shown in the following diagram:

diagram	
namespace	http://www.w3.org/2000/09/xmldsig#
annotation	Contains references to the signed parts of the package. The producer shall not create a Manifest element that references any data outside of the package. The consumer shall consider a Manifest element that references data outside of the package to be in error. [M6.22]

1

2 12.2.4.19 SignatureProperties Element

3 The structure of a SignaturePropertieselement is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#
Annotation	Contains additional information items concerning the generation of signatures placed in SignatureProperty elements.

4 12.2.4.20 SignatureProperty Element

5 The structure of a SignatureProperty element is shown in the following diagram:

diagram	namespace	http://www.w3.org/2000/09/xmldsig#

attributes

Name	Type	Use	Default	Fixed	Annotation
Target	xs:anyURI	required			Contains a unique identifier of the Signature element.
Id	xs:ID	optional			Contains signature property's unique identifier.

annotation	Contains additional information concerning the generation of signatures.

12.2.4.21 SignatureTime Element

The structure of a SignatureTime element is shown in the following diagram:

diagram	namespace	http://schemas.openxmlformats.org/package/2006/digital-signature
annotation	Holds the date/time stamp for the signature.

12.2.4.22 Format Element

The structure of a Format element is shown in the following diagram:

diagram	
namespace	http://schemas.openxmlformats.org/package/2006/digital-signature
annotation	Specifies the format of the date/time stamp. The producer shall create a data/time format that conforms to the syntax described in the W3C Note "Date and Time Formats". The consumer shall consider a format that does not conform to the syntax described in that WC3 note to be in error. [M6.23]

The date and time format definition conforms to the syntax described in the W3C Note “Date and Time Formats.”

12.2.4.23 Value Element

The structure of a Value element is shown in the following diagram:

diagram	
namespace	http://schemas.openxmlformats.org/package/2006/digital-signature
annotation	Holds the value of the date/time stamp. The producer shall create a value that conforms to the format specified in the Format element. The consumer shall consider a value that does not conform to that format to be in error. [M6.24]

12.2.4.24 RelationshipReference Element

The structure of a RelationshipReference element is shown in the following diagram:

diagram	
namespace	http://schemas.openxmlformats.org/package/2006/digital-signature
attributes	Name: SourceId; Type: xsd:string; Use: required; Default: ; Fixed: ; Annotation: Specifies the value of the Id attribute of the Relationship element.
annotation	Specifies the Relationship element to be signed.

12.2.4.25 RelationshipsGroupReference Element

The structure of a RelationshipsGroupReference element is shown in the following diagram:

diagram	
namespace	http://schemas.openxmlformats.org/package/2006/digital-signature
attributes	Name: SourceType; Type: xsd:anyURI; Use: required; Default: ; Fixed: ; Annotation: Specifies the value of the Type attribute of Relationship elements.
annotation	Specifies that the group of Relationship elements with the specified Type value is to be signed.

Format designers might permit producers to sign individual relationships in a package or the Relationships part as a whole. [O6.10] To sign a subset of relationships, the producer shall use the package-specific relationships transform. The consumer shall use the package-specific relationships transform to validate the signature when a subset of relationships are signed. [M6.25] The transform filters the contents of the Relationships part to include only relationships that have Id values matching the specified SourceId values or Type values matching the specified SourceType values. A producer shall not specify more than one relationship transform for a particular relationships part. A consumer shall treat the presence of more than one relationship transform for a particular relationships part as an error. [M6.35]

Producers shall specify a canonicalization transform immediately following a relationships transform and consumers that encounter a relationships transform that is not immediately followed by a canonicalization transform shall generate an error. [M6.26]

12.2.4.26 Relationships Transform Algorithm

The relationships transform takes the XML document from the Relationships part and converts it to another XML document.

The package implementer might create relationships XML that contains content from several namespaces, along with versioning instructions as defined in Part 5: “Markup Compatibility and Extensibility”. [O6.11]

The relationships transform algorithm is as follows:

Step 1: Process versioning instructions

1. The package implementer shall process the versioning instructions, considering that the only known namespace is the Relationships namespace.
2. The package implementer shall remove all ignorable content, ignoring preservation attributes.
3. The package implementer shall remove all versioning instructions.

Step 2: Sort and filter relationships

1. The package implementer shall remove all namespace declarations except the Relationships namespace declaration.
2. The package implementer shall remove the Relationships namespace prefix, if it is present.
3. The package implementer shall sort relationship elements by Id value in lexicographical order, considering Id values as case-sensitive Unicode strings.
4. The package implementer shall remove all Relationship elements that do not have eitheran Id value that matches any SourceId valueor a Type value that matches any SourceType value, among the SourceId and SourceType values specified in the transform definition. Producers and consumers shall compare values as case-sensitive Unicode strings. [M6.27] The resulting XML document holds all Relationship elements that either have an Id value that matches a SourceId value *or* a Type value that matches a SourceType value specified in the transform definition.

Step 3: Prepare for canonicalization

1. The package implementer shall remove all characters between the Relationships start tag and the first Relationship start tag.
2. The package implementer shall remove any contents of the Relationship element.
3. The package implementer shall remove all characters between the last Relationship end tag and the Relationships end tag.
4. If there are no Relationship elements, the package implementer shall remove all characters between the Relationships start tag and the Relationships end tag.

12.3 Digital Signature Example

The contents of digital signature parts are defined by the W3C Recommendation "XML-Signature Syntax and Processing" with some package-specific modifications specified in §12.2.4.1.

[*Example:*

Digital signature markup for packages is illustrated in this example. For information about namespaces used in this example, see Annex F, "Standard Namespaces and Content Types."

```
<Signature Id="SignatureId" xmlns="http://www.w3.org/2000/09/xmldsig#">
   <SignedInfo>
      <CanonicalizationMethod Algorithm="http://www.w3.org/TR/2001/
         REC-xml-c14n-20010315"/>
      <SignatureMethod Algorithm="http://www.w3.org/2000/09/
         xmldsig#dsa-sha1"/>

        </SignatureProperties>
     </Object>
     <Object Id="Application">...</Object>
  </Signature>
```

end example]

12.4 Generating Signatures

The steps for signing package contents follow the algorithm outlined in §3.1 of the W3C Recommendation "XML-Signature Syntax and Processing," with some modification for package-specific constructs.

The steps below might not be sufficient for generating signatures that contain application-specific Object elements. Format designers that utilize application-specific Object elements shall also define the additional steps that shall be performed to sign the application-specific Object elements.

To generate references:

1. For each package part being signed:
    a. The package implementer shall apply the transforms, as determined by the producer, to the contents of the part. [*Note:* Relationships transforms are applied only to Relationship parts. When applied, the relationship transform filters the subset of relationships within the entire Relationship part for purposes of signing. *end note*]
    b. The package implementer shall calculate the digest value using the resulting contents of the part.
2. The package implementer shall create a Reference element that includes the reference of the part with the query component matching the content type of the target part, necessary Transform elements, the DigestMethod element and the DigestValue element.
3. The package implementer shall construct the package-specific Object element containing a Manifest element with both the child Reference elements obtained from the preceding step and a child SignatureProperties element, which, in turn, contains a child SignatureTime element.
4. The package implementer shall create a reference to the resulting package-specific Object element.

When signing Object element data, package implementers shall follow the generic reference creation algorithm described in §3.1 of the W3C Recommendation "XML-Signature Syntax and Processing". [M6.28]

To generate signatures:

1. The package implementer shall create the SignedInfo element with a SignatureMethodelement, a CanonicalizationMethod element, and at least one Reference element.
2. The package implementer shall canonicalize the data and then calculate the SignatureValue element using the SignedInfo element based on the algorithms specified in the SignedInfo element.
3. The package implementer shall construct a Signature element that includes SignedInfo, Object, and SignatureValue elements. If a certificate is embedded in the signature, the package implementer shall also include the KeyInfo element.

12.5 Validating Signatures

Consumers validate signatures following the steps described in §3.2 of the W3C Recommendation "XML-Signature Syntax and Processing." When validating digital signatures, consumers shall verify the content type and the digest contained in each Reference descendant element of the SignedInfo element, and validate the signature calculated using the SignedInfo element. [M6.29]

The steps below might not be sufficient to validate signatures that contain application-specific Object elements. Format designers that utilize application-specific Object elements shall also define the additional steps that shall be performed to validate the application-specific Object elements.

To validate references:

1. The package implementer shall canonicalize the SignedInfo element based on the CanonicalizationMethod element specified in the SignedInfo element.
2. For each Reference element in the SignedInfo element:

    a. The package implementer shall obtain the Object element to be digested.
    b. For the package-specific Object element, the package implementer shall validate references to signed parts stored in the Manifest element. The package implementer shall consider references invalid if there is a missing part. [M6.9] [*Note:* If a relationships transform is specified for a signed Relationships part, only the specified subset of relationships within the entire Relationships part are validated. *end note*]
    c. For the package-specific Object element, validation of Reference elements includes verifying the content type of the referenced part and the content type specified in the reference query component. Package implementers shall consider references invalid if these two values are different. The string comparison shall be case-sensitive and locale-invariant. [M6.11]
    d. The package implementer shall digest the obtained Object element using the DigestMethod element specified in the Reference element.
    e. The package implementer shall compare the generated digest value against the DigestValue element in the Reference element of the SignedInfo element. Package implementers shall consider references invalid if there is any mismatch. [M6.30]

To validate signatures:

1. The package implementer shall obtain the public key information from the KeyInfo element or from an external source.

2. The package implementer shall obtain the canonical form of the SignatureMethod element using the CanonicalizationMethod element. The package implementer shall use the result and the previously obtained KeyInfo element to confirm the SignatureValue element stored in the SignedInfo element. The package implementer shall decrypt the SignatureValueelement using the public key prior to comparison.

12.5.1 Signature Validation and Streaming Consumption

Streaming consumers that maintain signatures shall be able to cache the parts necessary for detecting and processing signatures. [M6.31]

12.6 Support for Versioning and Extensibility

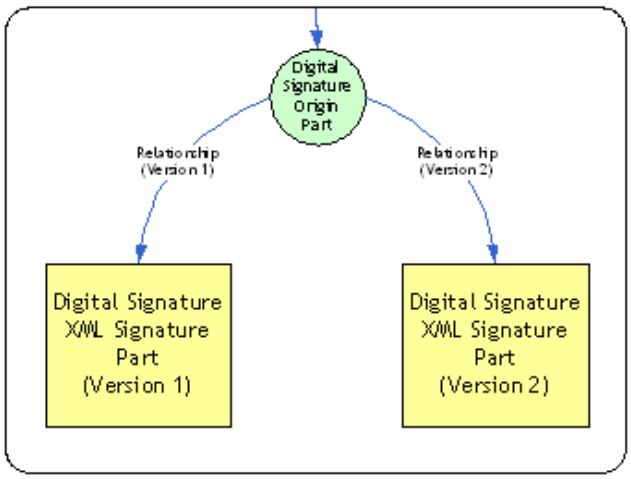
The package digital signature infrastructure supports the exchange of signed packages between current and future package clients.

12.6.1 Using Relationship Types

Future versions of the package format will specify distinct relationship types for revised signature parts. Using these relationships, producers will be able to store separate signature information for current and previous versions. Consumers will be able to choose the signature information they know how to validate.

Figure 12–2, “Part names and logical item names”, illustrates this versioning capability that will be available in future versions of the package format.

Figure 12–2. A package containing versioned signatures



12.6.2 Markup Compatibility Namespace for Package Digital Signatures

The package implementer shall not use the Markup Compatibility namespace, as specified in Annex F, “Standard Namespaces and Content Types,” within the package-specific Object element. The package implementer shall consider the use of the Markup Compatibility namespace within the package-specific Object element to be an error. [M6.32]

Format designers might specify an application-specific package part format that allows for the embedding of versioned or extended content that might not be fully understood by all present and future implementations. Producers might create such embedded versioned or extended content and consumers might encounter such content. [O6.12] [*Example*: An XML package part format might rely on Markup Compatibility elements and attributes to embed such versioned or extended content. *end example]*

If an application allows for a single part to contain information that might not be fully understood by all implementations, then the format designer shall carefully design the signing and verification policies to account for the possibility of different implementations being used for each action in the sequence of content creation, content signing, and signature verification. Producers and consumers shall account for this possibility in their signing and verification processing. [M6.33]

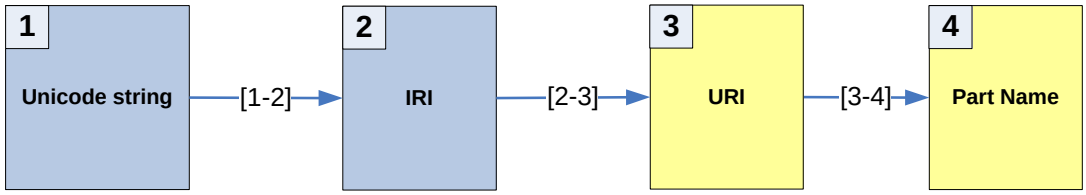
Annex A. Resolving Unicode Strings to Part Names

Package clients might use Unicode strings for referencing parts in a package. [*Example*: Values of xsd:anyURI data type within XML markup are Unicode strings. *end example]*

This annex specifies how such Unicode strings shall be resolved to part names.

The diagram below illustrates the conversion path from the Unicode string to a part name. The numbered arcs identify string transformations.

Figure A–1. Strings are converted to part names for referencing parts



A Unicode string representing a URI can be passed to the producer or consumer. The producing or consuming application shall convert the Unicode string to a URI. If the URI is a relative reference, the application shall resolve it using the base URI of the part, which is expressed using the pack scheme, to the URI of the referenced part. [M1.33]

The process for resolving a Unicode string to a part name follows Arcs [1-2], [2-3], and [3-4].

A.1 Creating an IRI from a Unicode String

With reference to Arc [1-2] in Figure A–1, a Unicode string is converted to an IRI by percent-encoding each ASCII character that does not belong to the set of reserved or unreserved characters as defined in RFC 3986.

A.2 Creating a URI from an IRI

With reference to Arc [2-3] in Figure A–1, an IRI is converted to a URI by converting non-ASCII characters as defined in Step 2 in §3.1 of RFC 3987

If a consumer converts the URI back into an IRI, the conversion shall be performed as specified in §3.2 of RFC 3987. [M1.34]

A.3 Resolving a Relative Reference to a Part Name

If the URI reference obtained in §A.2 is a URI, it is resolved in the regular way, that is, with no package-specific considerations. Otherwise, if the URI reference is a relative reference, it is resolved (with reference to Arc [3-4] in Figure A–1) as follows:

1. Percent-encode each open bracket ([) and close bracket (]).
2. Percent-encode each percent (%) character that is not followed by a hexadecimal notation of an octet value.
3. Un-percent-encode each percent-encoded unreserved character.
4. Un-percent-encode each forward slash (/) and back slash (\).
5. Convert all back slashes to forward slashes.
6. If present in a segment containing non-dot (“.”) characters, remove trailing dot (“.”) characters from each segment.
7. Replace each occurrence of multiple consecutive forward slashes (/) with a single forward slash.
8. If a single trailing forward slash (/) is present, remove that trailing forward slash.
9. Remove complete segments that consist of three or more dots.
10. Resolve the relative reference against the base URI of the part holding the Unicode string, as it is defined in §5.2 of RFC 3986. The path component of the resulting absolute URI is the part name.

A.4 String Conversion Examples

[*Example:*

Examples of Unicode strings converted to IRIs, URIs, and part names are shown below:

Unicode string	IRI	URI	Part name
/a/b.xml	/a/b.xml	/a/b.xml	/a/b.xml
/a/ц.xml	/a/ц.xml	/a/%D1%86.xml	/a/%D1%86.xml
/%41/%61.xml	/%41/%61.xml	/%41/%61.xml	/A/a.xml

end example]

Annex B. Pack URI

A package is a logical entity that holds a collection of parts. This Open Packaging specification defines a way to use URIs to reference part resources inside a package. This approach defines a new scheme in accordance with the guidelines in RFC 3986.

The following terms are used as they are defined in RFC 3986: *scheme*, *authority*, *path*, *segment*, *reserved characters*, *sub-delims*, *unreserved characters*, *pchar*, *pct-encoded characters*, *query*, *fragment*, and *resource*.

B.1 Pack URI Scheme

RFC 3986 provides an extensible mechanism for defining new kinds of URIs based on new schemes. Schemes are the prefix in a URI before the colon. [*Example*: “http”, “ftp”, “file” *end example*] This Open Packaging specification defines a specific URI scheme used to refer to parts in a package: the pack scheme. A URI that uses the pack scheme is called a *pack URI*.

The pack URI grammar is defined as follows:

```
pack_URI  = "pack://" authority [ "/" | path ]
authority = *( unreserved | sub-delims | pct-encoded )
path      = 1*( "/" segment )
segment   = 1*( pchar )
```

unreserved, sub-delims, pchar and pct-encoded are defined in RFC 3986

The authority component contains an embedded URI that points to a package. The package implementer shall create an embedded URI that meets the requirements defined in RFC 3986 for a valid URI. [M7.1] §B.3 describes the rules for composing pack URIs by combining the URI of an entire package resource with a part name.

The package implementer shall not create an authority component with an unescaped colon (:) character. [M7.4] Consumer applications, based on the obsolete URI specification RFC 2396, might tolerate the presence of an unescaped colon character in an authority component. [O7.1]

The optional path component identifies a particular part within the package. The package implementer shall only create path components that conform to the part naming rules. When the path component is missing, the resource identified by the pack URI is the package as a whole. [M7.2]

In order to be able to embed the URI of the package in the pack URI, it is necessary either to replace or to percent-encode occurrences of certain characters in the embedded URI. For example, forward slashes (/) are replaced with commas (,). The rules for these substitutions are described in §B.3.

The optional query component in a pack URI is ignored when resolving the URI to a part.

A pack URI might have a fragment identifier as specified in RFC 3986. If present, this fragment applies to whatever resource the pack URI identifies.

[*Example:*

Example B–1. Using the pack URI to identify a part

The following URI identifies the "/a/b/foo.xml" part within the "http://www.openxmlformats.org/my.container" package resource:

```
pack://http%3c,,www.openxmlformats.org,my.container/a/b/foo.xml
```

end example]

[*Example:*

Example B–2. Equivalent pack URIs

The following pack URIs are equivalent:

```
pack://http%3c,,www.openxmlformats.org,my.container
pack://http%3c,,www.openxmlformats.org,my.container/
```

end example]

[*Example:*

Example B–3. A pack URI with percent-encoded characters

The following URI identifies the "/c/d/bar.xml" part within the "http://myalias:pswr@www.my.com/containers.aspx?my.container" package:

```
pack://http%3c,,myalias%3cpswr%40www.my.com,containers.aspx%3fmy.container
/c/d/bar.xml
```

end example]

B.2 Resolving a Pack URI to a Resource

The following is an algorithm for resolving a pack URI to a resource (either a package or a part):

1. Parse the pack URI into the potential three components: scheme, authority, path, as well as any fragment identifier.
2. In the authority component, replace all commas (,) with forward slashes (/).
3. Un-percent-encode ASCII characters in the resulting authority component.
4. The resultant authority component is the URI for the package as a whole.
5. If the path component is empty, the pack URI resolves to the package as a whole and the resolution process is complete.

6. A non-empty path component shall be a valid part name. If it is not, the pack URI is invalid.
7. The pack URI resolves to the part with this part name in the package identified by the authority component.

[*Example:*

Example B–4. Resolving a pack URI to a resource

Given the pack URI:

```
pack://http%3c,,www.my.com,packages.aspx%3fmy.package/a/b/foo.xml
```

The components:

```
<authority>= http%3c,,www.my.com,packages.aspx%3fmy.package
<path>= /a/b/foo.xml
```

Are converted to the package URI:

```
http://www.my.com/packages.aspx?my.package
```

And the path:

```
/a/b/foo.xml
```

Therefore, this URI refers to a part named "/a/b/foo.xml" in the package at the following URI: http://www.my.com/packages.aspx?my.package.

end example]

B.3 Composing a Pack URI

The following is an algorithm for composing a pack URI from the URI of an entire package resource and a part name.

In order to be suitable for creating a pack URI, the URI reference of a package resource shall conform to RFC 3986 requirements for valid absolute URIs.

To compose a pack URI from the absolute package URI and a part name, the following steps shall be performed, in order:

1. Remove the fragment identifier from the package URI, if present.
2. Percent-encode all percent signs (%), question marks (?), at signs (@), colons (:) and commas (,) in the package URI.
3. Replace all forward slashes (/) with commas (,) in the resulting string.
4. Append the resulting string to the string "pack://".
5. Append a forward slash (/) to the resulting string. The constructed string represents a pack URI with a blank path component.

6. Using this constructed string as a base URI and the part name as a relative reference, apply the rules defined in RFC 3986 for resolving relative references against the base URI.

The result of this operation will be the pack URI that refers to the resource specified by the part name.

[*Example:*

Example B–5. Composing a pack URI

Given the package URI:

```
http://www.my.com/packages.aspx?my.package
```

And the part name:

```
/a/foo.xml
```

The pack URI is:

```
pack://http%3c,,www.my.com,packages.aspx%3fmy.package/a/foo.xml
```

end example]

B.4 Equivalence

In some scenarios, such as caching or writing parts to a package, it is necessary to determine if two pack URIs are equivalent without resolving them.

The package implementer shall consider pack URIs equivalent if:

1. The scheme components are octet-by-octet identical after they are both converted to lowercase; *and*
2. The URIs, decoded as described in §B.2 from the authority components are equivalent (the equivalency rules by scheme, as per RFC 3986); *and*
3. The path components are equivalent when compared as case-insensitive ASCII strings.

[M7.3]

Annex C. ZIP Appnote.txt Clarifications

The ZIP specification includes a number of features that packages do not support. Some ZIP features are clarified in the context of this Open Packaging specification. Package producers and consumers shall adhere to the requirements noted below.

C.1 Archive File Header Consistency

Data describing files stored in the archive is substantially duplicated in the Local File Headers and Data Descriptors, and in the File headers within the Central Directory Record. For a ZIP archive to be a valid physical layer for a package, the package implementer shall ensure that the ZIP archive holds equal values in the appropriate fields of every File Header within the Central Directory and the corresponding Local File Header and Data Descriptor pair. [M3.14]

C.2 Table Key

- "Yes" — During consumption of a package, a "Yes" value for a field in a table in Annex C indicates a package implementer shall support reading the ZIP archive containing this record or field, however, support may mean ignoring. [M3.15] During production of a package, a "Yes" value for a field in a table in Annex C indicates that the package implementer shall write out this record or field. [M3.16]
- "No" — A "No" value for a field in a table in Annex C indicates the package implementer shall not use this record or field during consumption or production of packages. [M3.17]
- "Optional" — An "Optional" value for a record in a table in Annex C indicates that package implementers might write this record during production. [O3.2]
- "Partially, details below" — A "Partially, details below" value for a record in a table in Annex C indicates that the record contains fields that might not be supported by package implementers during production or consumption. See the details in the corresponding table to determine requirements. [M3.18]
- "Only used when needed" — The value "Only used when needed" associated with a record in a table in Annex C indicates that the package implementer shall use the record only when needed to store data in the ZIP archive. [M3.19]

Table C–1,"Support for records", specifies the requirements for package production, consumption, and editing in regard to particular top-level records or fields described in the ZIP Appnote.txt. [*Note:* Editing, in this context, means in-place modification of individual records. A format specification can require editing applications to instead modify content in-memory and re-write all parts and relationships on each save in order to maintain more rigorous control of ZIP record usage. *end note*]

Table C–1. Support for records

Record name	Supported on Consumption	Supported on Production	Pass through on editing

Record name	Supported on Consumption	Supported on Production	Pass through on editing
Local File Header	Yes (partially, details below)	Yes (partially, details below)	Yes
File data	Yes	Yes	Yes
Data descriptor	Yes	Optional	Optional
Archive decryption header	No	No	No
Archive extra data record	No	No	No
Central directory structure: File header	Yes (partially, details below)	Yes (partially, details below)	Yes
Central directory structure: Digital signature	Yes (ignore the signature data)	Optional	Optional
Zip64 end of central directory record V1 (from spec version 4.5)	Yes (partially, details below)	Yes (partially, details below, used only when needed)	Optional
Zip64 end of central directory record V2 (from spec version 6.2)	No	No	No
Zip64 end of central directory locator	Yes (partially, details below)	Yes (partially, details below, used only when needed)	Optional
End of central directory record	Yes (partially, details below)	Yes (partially, details below, used only when needed)	Yes

Table C–2, “Support for record components”, specifies the requirements for package production, consumption, and editing in regard to individual record components described in the ZIP Appnote.txt.

Table C–2. Support for record components

Record	Field	Supported on Consumption	Supported on Production	Pass through on editing
Local File Header	Local file header signature	Yes	Yes	Yes
	Version needed to extract	Yes (partially, see Table C–3)	Yes (partially, see Table C–3)	Yes (partially, see Table C–3)

Record	Field	Supported on Consumption	Supported on Production	Pass through on editing
	General purpose bit flag	Yes (partially, see Table C–5)	Yes (partially, see Table C–5)	Yes (partially, see Table C–5)
	Compression method	Yes (partially, see Table C–4)	Yes (partially, see Table C–4)	Yes (partially, see Table C–4)
	Last mod file time	Yes	Yes	Yes
	Last mod file date	Yes	Yes	Yes
	Crc-32	Yes	Yes	Yes
	Compressed size	Yes	Yes	Yes
	Uncompressed size	Yes	Yes	Yes
	File name length	Yes	Yes	Yes
	Extra field length	Yes	Yes	Yes
	File name (variable size)	Yes	Yes	Yes
	Extra field (variable size)	Yes (partially, see Table C–6)	Yes (partially, see Table C–6)	Yes (partially, see Table C–6)
Central directory structure: File header	Central file header signature	Yes	Yes	Yes
	version made by: high byte	Yes	Yes (0 = MS-DOS is default publishing value)	Yes
	Version made by: low byte	Yes	Yes	Yes
	Version needed to extract (see Table C–3 for details)	Yes (partially, see Table C–3)	Yes (1.0, 1.1, 2.0, 4.5)	Yes
	General purpose bit flag	Yes (partially, see Table C–5)	Yes (partially, see Table C–5)	Yes (partially, see Table C–5)
	Compression method	Yes (partially, see Table C–4)	Yes (partially, see Table C–4)	Yes (partially, see Table C–4)
	Last mod file time (Pass through, no interpretation)	Yes	Yes	Yes
	Last mod file date (Pass through, in interpretation)	Yes	Yes	Yes
	Crc-32	Yes	Yes	Yes
	Compressed size	Yes	Yes	Yes
	Uncompressed size	Yes	Yes	Yes
	File name length	Yes	Yes	Yes
	Extra field length	Yes	Yes	Yes

Record	Field	Supported on Consumption	Supported on Production	Pass through on editing
	File comment length	Yes	Yes (always set to 0)	Yes
	Disk number start	Yes (partial — no multi disk archives)	Yes (always 1 disk)	Yes (partial — no multi disk archives)
	Internal file attributes	Yes	Yes	Yes
	External file attributes (Pass through, no interpretation)	Yes	Yes (MS DOS default value)	Yes
	Relative offset of local header	Yes	Yes	Yes
	File name (variable size)	Yes	Yes	Yes
	Extra field (variable size)	Yes (partially, see Table C–6)	Yes (partially, see Table C–6)	Yes (partially, see Table C–6)
	File comment (variable size)	Yes	Yes (always set to empty)	Yes
Zip64 end of central directory V1 (from spec version 4.5, only used when needed)	Zip64 end of central directory signature	Yes	Yes	Yes
	Size of zip64 end of central directory	Yes	Yes	Yes
	Version made by: high byte (Pass through, no interpretation)	Yes	Yes (0 = MS-DOS is default publishing value)	Yes
	Version made by: low byte	Yes	Yes (always 4.5 or above)	Yes
	Version needed to extract (see Table C–3 for details)	Yes (4.5)	Yes (4.5)	Yes (4.5)
	Number of this disk	Yes (partial — no multi disk archives)	Yes (always 1 disk)	Yes (partial — no multi disk archives)
	Number of the disk with the start of the central directory	Yes (partial — no multi disk archives)	Yes (always 1 disk)	Yes (partial — no multi disk archives)
	Total number of entries in the central directory on this disk	Yes	Yes	Yes
	Total number of entries in the central directory	Yes	Yes	Yes

Record	Field	Supported on Consumption	Supported on Production	Pass through on editing
	Size of the central directory	Yes	Yes	Yes
	Offset of start of central directory with respect to the starting disk number	Yes	Yes	Yes
	Zip64 extensible data sector	Yes	No	Yes
Zip64 end of central directory locator (only used when needed)	Zip64 end of central dir locator signature	Yes	Yes	Yes
	Number of the disk with the start of the zip64 end of central directory	Yes (partial — no multi disk archives)	Yes (always 1 disk)	Yes (partial — no multi disk archives)
	Relative offset of the zip64 end of central directory record	Yes	Yes	Yes
	Total number of disks	Yes (partial — no multi disk archives)	Yes (always 1 disk)	Yes (partial — no multi disk archives)
End of central directory record	End of central dir signature	Yes	Yes	Yes
	Number of this disk	Yes (partial — no multi disk archives)	Yes (always 1 disk)	Yes (partial — no multi disk archives)
	Number of the disk with the start of the central directory	Yes (partial — no multi disk archive)	Yes (always 1 disk)	Yes (partial — no multi disk archive)
	Total number of entries in the central directory on this disk	Yes	Yes	Yes
	Total number of entries in the central directory	Yes	Yes	Yes
	Size of the central directory	Yes	Yes	Yes
	Offset of start of central directory with respect to the starting disk number	Yes	Yes	Yes
	ZIP file comment length	Yes	Yes	Yes
	ZIP file comment	Yes	No	Yes

1

Table C–3, “Support for Version Needed to Extract field”, specifies the detailed production, consumption, and editing requirements for the Extract field, which is fully described in the ZIP Appnote.txt.

Table C–3. Support for Version Needed to Extract field

Version	Feature	Supported on Consumption	Supported on Production	Pass through on editing
1.0	Default value	Yes	Yes	Yes
1.1	File is a volume label	Ignore	No	(rewrite/remove)
2.0	File is a folder (directory)	Ignore	No	(rewrite/remove)
2.0	File is compressed using Deflate compression	Yes	Yes	Yes
2.0	File is encrypted using traditional PKWARE encryption	No	No	No
2.1	File is compressed using Deflate64(tm)	No	No	No
2.5	File is compressed using PKWARE DCL Implode	No	No	No
2.7	File is a patch data set	No	No	No
4.5	File uses ZIP64 format extensions	Yes	Yes	Yes
4.6	File is compressed using BZIP2 compression	No	No	No
5.0	File is encrypted using DES	No	No	No
5.0	File is encrypted using 3DES	No	No	No
5.0	File is encrypted using original RC2 encryption	No	No	No
5.0	File is encrypted using RC4 encryption	No	No	No
5.1	File is encrypted using AES encryption	No	No	No
5.1	File is encrypted using corrected RC2 encryption	No	No	No
5.2	File is encrypted using corrected RC2-64 encryption	No	No	No
6.1	File is encrypted using non-OAEP key wrapping	No	No	No
6.2	Central directory encryption	No	No	No

Table C–4, “Support for Compression Method field”, specifies the detailed production, consumption, and editing requirements for the Compression Method field, which is fully described in the ZIP Appnote.txt.

Table C–4. Support for Compression Method field

Code	Method	Supported on Consumption	Supported on Production	Pass through on editing
0	The file is stored (no compression)	Yes	Yes	Yes
1	The file is Shrunk	No	No	No
2	The file is Reduced with compression factor 1	No	No	No
3	The file is Reduced with compression factor 2	No	No	No
4	The file is Reduced with compression factor 3	No	No	No
5	The file is Reduced with compression factor 4	No	No	No
6	The file is Imploded	No	No	No
7	Reserved for Tokenizing compression algorithm	No	No	No
8	The file is Deflated	Yes	Yes	Yes
9	Enhanced Deflating using Deflate64™	No	No	No
10	PKWARE Data Compression Library Imploding	No	No	No
11	Reserved by PKWARE	No	No	No

Table C–5, “Support for modes/structures defined by general purpose bit flags”, specifies the detailed production, consumption, and editing requirements when utilizing these general-purpose bit flags within records.

Table C–5. Support for modes/structures defined by general purpose bit flags

Bit	Feature	Supported on Consumption	Supported on Production	Pass through on editing
0	If set, indicates that the file is encrypted.	No	No	No

<table>
<tr><th>Bit</th><th>Feature</th><th>Supported on Consumption</th><th>Supported on Production</th><th>Pass through on editing</th></tr>
<tr><td>1, 2</td><td><table>
<tr><th>Bit 2</th><th>Bit 1</th><th></th></tr>
<tr><td>0</td><td>0</td><td>Normal (-en) compression option was used.</td></tr>
<tr><td>0</td><td>1</td><td>Maximum (-exx/-ex) compression option was used.</td></tr>
<tr><td>1</td><td>0</td><td>Fast (-ef) compression option was used.</td></tr>
<tr><td>1</td><td>1</td><td>Super Fast (-es) compression option was used.</td></tr>
</table></td><td>Yes</td><td>Yes</td><td>Yes</td></tr>
<tr><td>3</td><td>If this bit is set, the fields crc-32, compressed size and uncompressed size are set to zero in the local header. The correct values are put in the data descriptor immediately following the compressed data. (PKZIP version 2.04g for DOS only recognizes this bit for method 8 compression, newer versions of PKZIP recognize this bit for any compression method.)</td><td>Yes</td><td>Yes</td><td>Yes</td></tr>
<tr><td>4</td><td>Reserved for use with method 8, for enhanced deflating</td><td>Ignore</td><td>Bits set to 0</td><td>Yes</td></tr>
<tr><td>5</td><td>If this bit is set, this indicates that the file is compressed patched data. (Requires PKZIP version 2.70 or greater.)</td><td>Ignore</td><td>Bits set to 0</td><td>Yes</td></tr>
<tr><td>6</td><td>Strong encryption. If this bit is set, you should set the version needed to extract value to at least 50 and you must also set bit 0. If AES encryption is used, the version needed to extract value must be at least 51.</td><td>Ignore</td><td>Bits set to 0</td><td>Yes</td></tr>
<tr><td>7</td><td>Currently unused</td><td>Ignore</td><td>Bits set to 0</td><td>Yes</td></tr>
<tr><td>8</td><td>Currently unused</td><td>Ignore</td><td>Bits set to 0</td><td>Yes</td></tr>

0x756e	ASi Unix	Ignore	No	Yes
0x7855	Info-ZIP Unix (new)	Ignore	No	Yes
0xa220	Padding, Microsoft	Optional	Optional	Optional
0xfd4a	SMS/QDOS	Ignore	No	Yes

The package implementer shall ensure that all 64-bit stream record sizes and offsets have the high-order bit = 0. [M3.20]

The package implementer shall ensure that all fields that contain “number of entries” do not exceed 2,147,483,647. [M3.21]

Annex D. Schemas - XML Schema

This Open Packaging Conventions specification includes a family of schemas defined using the XML Schema 1.0 syntax. The normative definitions of these schemas reside in an accompanying file named OpenPackagingConventions-XMLSchema.zip, which is distributed in electronic form only.

If discrepancies exist between the electronic version of a schema and its corresponding representation as published in this part, Part 2, the electronic version is the definitive version.

Annex E. Schemas - RELAX NG

This clause is informative.

This Open Packaging Conventions specification includes a family of schemas defined using the RELAX NG syntax. The definitions of these schemas reside in an accompanying file named OpenPackagingConventions-RELAXNG.zip, which is distributed in electronic form only.

If discrepancies exist between the RELAX NG version of a schema and its corresponding XML Schema, the XML Schema is the definitive version.

End of informative text.

Annex F. Standard Namespaces and Content Types

The namespaces available for use in a package are listed in Table F–1, Package-wide namespaces

Table F–1. Package-wide namespaces

Description	Namespace URI
Content Types	http://schemas.openxmlformats.org/package/2006/content-types
Core Properties	http://schemas.openxmlformats.org/package/2006/metadata/core-properties
Digital Signatures	http://schemas.openxmlformats.org/package/2006/digital-signature
Relationships	http://schemas.openxmlformats.org/package/2006/relationships
Markup Compatibility	http://schemas.openxmlformats.org/markup-compatibility/2006

The content types available for use in a package are listed in Table F–2, Package-wide content types

Table F–2. Package-wide content types

Description	Content Type
Core Properties part	application/vnd.openxmlformats-package.core-properties+xml
Digital Signature Certificate part	application/vnd.openxmlformats-package.digital-signature-certificate
Digital Signature Origin part	application/vnd.openxmlformats-package.digital-signature-origin
Digital Signature XML Signature part	application/vnd.openxmlformats-package.digital-signature-xmlsignature+xml
Relationships part	application/vnd.openxmlformats-package.relationships+xml

Package implementers and format designers shall not create content types with parameters for the package-specific parts defined in this Open Packaging specification and shall treat the presence of parameters in these content types as an error. [M1.22]

The relationship types available for use in a package are listed in Table F–3, Package-wide relationship types.

Table F–3. Package-wide relationship types

Description	Relationship Type
Core Properties	http://schemas.openxmlformats.org/package/2006/relationships/metadata/core-properties

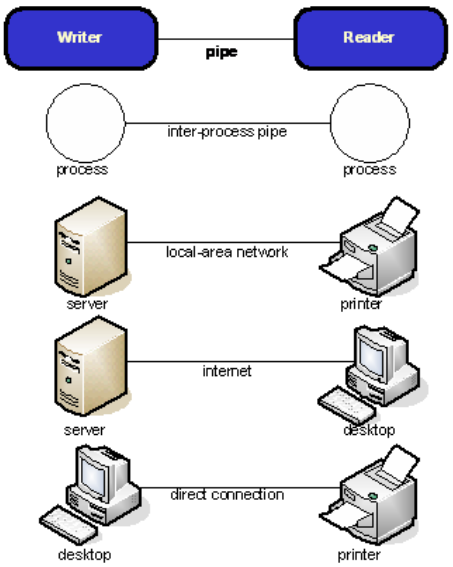
Annex G. Physical Model Design Considerations

This annex is informative.

The physical model defines the ways in which packages are produced and consumed. This model is based on three components: a producer, a consumer, and a pipe between them.

Figure G–1. Components of the physical model



A *producer* is a piece of software or a device that *writes* packages. A *consumer* is a piece of software or a device that *reads* packages. A *device* is a piece of hardware, such as a printer or scanner that performs a single function or set of functions. Data is carried from the producer to the consumer by a *pipe*.

In *local access*, the pipe carries data directly from a producer to a consumer on a single device.

In *networked access* the consumer and the producer communicate with each other over a protocol. The significant communication characteristics of this pipe are speed and request latency. For example, this communication might occur across a process boundary or between a server and a desktop computer.

In order to maximize performance, designers of physical package formats consider access style, layout style, and communication style.

G.1 Access Styles

The *access style* in which local access or networked access is conducted determines the simultaneity possible between processing and input-output operations.

G.1.1 Direct Access Consumption

Direct access consumption allows consumers to request the specific portion of the package desired, without sequentially processing the preceding parts of the package. For example a byte-range request. This is the most common access style.

G.1.2 Streaming Consumption

Streaming consumption allows consumers to begin processing parts before the entire package has arrived. Physical package formats should be designed to allow consumers to begin interpreting and processing the data they receive before all of the bits of the package have been delivered through the pipe.

G.1.3 Streaming Creation

Streaming creation allows producers to begin writing parts to the package without knowing in advance all of the parts that will be written. For example, when an application begins to build a print spool file package, it may not know how many pages the package will contain. Likewise, a program that is generating a report may not know initially how long the report will be or how many pictures it will have.

In order to support streaming creation, the package implementer should allow a producer to add parts after other parts have already been added. A Consumer shall not require a producer to state how many parts they will create when they start writing. The package implementer should allow a producer to begin writing the contents of a part without knowing the ultimate length of the part.

G.1.4 Simultaneous Creation and Consumption

Simultaneous creation and consumption allows streaming creation and streaming consumption to happen at the same time on a package. Because of the benefits that can be realized within pipelined architectures that use it, the package implementer should support simultaneous creation and consumption in the physical package.

G.2 Layout Styles

The style in which parts are ordered within a package is referred to as the *layout style*. Parts can be arranged in one of two styles: simple ordering or interleaved ordering.

G.2.1 Simple Ordering

With *simple ordering*, parts are arranged contiguously. When a package is delivered sequentially, all of the bytes for the first part arrive first, followed by all of the bytes for the second part, and so on. When such a package uses simple ordering, all of the bytes for each part are stored contiguously.

G.2.2 Interleaved Ordering

With *interleaved ordering*, pieces of parts are interleaved, allowing optimal performance in certain scenarios. For example, interleaved ordering improves performance for multi-media playback, where video and audio are delivered simultaneously and inline resource referencing, where a reference to an image occurs within markup.

By breaking parts into pieces and interleaving those pieces, it is possible to optimize performance while allowing easy reconstruction of the original contiguous part.

Because of the performance benefits it provides, package implementers should support interleaving in the physical package. The package implementer might handle the internal representation of interleaving differently in different physical models. Regardless of how the physical model handles interleaving, a part that is broken into multiple pieces in the physical file is considered one logical part; the pieces themselves are not parts and are not addressable.

G.3 Communication Styles

The style in which a package and its parts are delivered by a producer or accessed by a consumer is referred to as the *communication style*. Communication can be based on sequential delivery of or random access to parts. The communication style used depends on the capabilities of both the pipe and the physical package format.

G.3.1 Sequential Delivery

With *sequential delivery*, all of the physical bits in the package are delivered in the order they appear in the. Generally, all pipes support sequential delivery.

G.3.2 Random Access

Random access allows consumers to request the delivery of a part out of sequential physical order. Some pipes are based on protocols that can enable random access. For example, HTTP 1.1 with byte-range support. In order to maximize performance, the package implementer should support random access in both the pipe and the physical package. In the absence of this support, consumers need to wait until the parts they need are delivered sequentially.

End of informative text.

Annex H. Conformance Requirements

This annex is informative.

This annex summarizes all conformance requirements for producers and consumers implementing the Open Packaging Conventions. It is intended as a convenience; the text in the referenced clause or subclause is considered normative in all cases.

Conformance requirements are divided into tables based on their general topic below. The tables contain the requirements that producers and consumers shall follow, those that they should follow, and those that are optional. Each conformance requirement is given a unique ID comprised of a letter (M – MANDATORY; S – SHOULD; O – OPTIONAL), an identifier for the topic it relates to, and a unique ID within that topic. Mandatory requirements are those stated with the normative terms "shall," "shall not," or any of their normative equivalents. Should items are those stated with the normative terms "should," "should not," or any of their normative equivalents. Optional requirements are those stated with the normative terms "can," "cannot," "might," "might not," or any of their normative equivalents.

Producers and consumers might use these IDs to report error conditions.

The top-level topics and their identifiers are described as follows:

1. Package Model requirements
2. Physical Packages requirements
3. ZIP Physical Mapping requirements
4. Core Properties requirements
5. Thumbnail requirements
6. Digital Signatures requirements
7. Pack URI requirements

Additionally, these tables identify, as does the referenced text, who is burdened with enforcing or supporting the requirement:

H.1 Package Model

Table H–1. Package model conformance requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M1.1	The package implementer shall require a part name.	8.1, 8.1.1	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M1.2	The package implementer shall require a content type and the format designer shall specify the content type.	8.1	×	×		
M1.3	A part name shall not have empty segments.	0	×			
M1.4	A part name shall start with a forward slash (“/”) character.	0	×			
M1.5	A part name shall not have a forward slash as the last character.	0	×			
M1.6	A segment shall not hold any characters other than pchar characters. .	0	×			
M1.7	A segment shall not contain percent-encoded forward slash (“/”), or backward slash (“\”) characters.	0	×			
M1.8	A segment shall not contain percent-encoded unreserved characters.	0	×			
M1.9	A segment shall not end with a dot (“.”) character.	0	×			
M1.10	A segment shall include at least one non-dot character	0	×			
M1.11	A package implementer shall neither create nor recognize a part with a part name derived from another part name by appending segments to it.	8.1.1.1	×			
M1.12	Part name equivalence is determined by comparing part names as case-insensitive ASCII strings. Packages shall not contain equivalent part names and package implementers shall neither create nor recognize packages with equivalent part names.	8.1.1.2	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M1.13	Package implementers shall only create and only recognize parts with a content type; format designers shall specify a content type for each part included in the format. Content types for package parts shall fit the definition and syntax for media types as specified in RFC 2616, §3.7.	8.1.2	×	×		
M1.14	Content types shall not use linear white space either between the type and subtype or between an attribute and its value. Content types also shall not have leading or trailing white spaces. Package implementers shall create only such content types and shall require such content types when retrieving a part from a package; format designers shall specify only such content types for inclusion in the format.	8.1.2	×	×		
M1.15	The package implementer shall require a content type that does not include comments and the format designer shall specify such a content type.	8.1.2	×	×		
M1.16	If the package implementer specifies a growth hint, it is set when a part is created and the package implementer shall not change the growth hint after the part has been created.	8.1.3	×		×	

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M1.17	XML content shall be encoded using either UTF-8 or UTF-16. If any part includes an encoding declaration, as defined in §4.3.3 of the XML 1.0 specification, that declaration shall not name any encoding other than UTF-8 or UTF-16. Package implementers shall enforce this requirement upon creation and retrieval of the XML content.	8.1.4	×			
M1.18	DTD declarations shall not be used in the XML markup defined in this Open Packaging specification. Package implementers shall enforce this requirement upon creation and retrieval of the XML content and shall treat the presence of DTD declarations as an error.	8.1.4	×			
M1.19	If the XML content contains the Markup Compatibility namespace, as described in Part 5: “Markup Compatibility and Extensibility”, it shall be processed by the package implementer to remove Markup Compatibility elements and attributes, ignorable namespace declarations, and ignored elements and attributes before applying subsequent validation rules.	8.1.4	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M1.20	XML content shall be valid against the corresponding XSD schema defined in this Open Packaging specification. In particular, the XML content shall not contain elements or attributes drawn from namespaces that are not explicitly defined in the corresponding XSD unless the XSD allows elements or attributes drawn from any namespace to be present in particular locations in the XML markup. Package implementers shall enforce this requirement upon creation and retrieval of the XML content.	8.1.4	×			
M1.21	XML content shall not contain elements or attributes drawn from “xml” or “xsi” namespaces unless they are explicitly defined in the XSD schema or by other means described in this Open Packaging specification. Package implementers shall enforce this requirement upon creation and retrieval of the XML content.	8.1.4	×			
M1.22	Package implementers and format designers shall not create content types with parameters for the package-specific parts defined in this Open Packaging specification and shall treat the presence of parameters in these content types as an error.	Annex F	×	×		

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M1.23	XML markup might contain Unicode strings referencing other parts as values of the xsd:anyURI data type. Format consumers shall convert these Unicode strings to URIs, as defined in Annex A, “Resolving Unicode Strings to Part Names,” before resolving them relative to the base URI of the part containing the Unicode string.	8.2.1				×
M1.24	Some types of content provide a way to override the default base URI by specifying a different base in the content. In the presence of one of these overrides, format consumers shall use the specified base URI instead of the default.	8.2.1				×
M1.25	The Relationships part shall not have relationships to any other part. Package implementers shall enforce this requirement upon the attempt to create such a relationship and shall treat any such relationship as invalid.	8.3.1	×			
M1.26	The package implementer shall require that every Relationship element has an Id attribute, the value of which is unique within the Relationships part, and that the Id type is xsd:ID, the value of which conforms to the naming restrictions for xsd:ID as described in the W3C Recommendation “XML Schema Part 2: Datatypes.”	8.3.3	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M1.27	The package implementer shall require the Type attribute to be a URI that defines the role of the relationship and the format designer shall specify such a Type.	8.3.3.2	×	×		
M1.28	The package implementer shall require the Target attribute to be a URI reference pointing to a target resource. The URI reference shall be a URI or a relative reference.	8.3.3.2	×			
M1.29	When set to Internal, the Target attribute shall be a relative reference and that reference is interpreted relative to the “parent” part. For package relationships, the package implementer shall resolve relative references in the Target attribute against the pack URI that identifies the entire package resource.	8.3.3.2	×			
M1.30	The package implementer shall name relationship parts according to the special relationships part naming convention and require that parts with names that conform to this naming convention have the content type for a Relationships part	8.3.4	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M1.31	Consumers shall process relationship markup in a manner that conforms to Part 5: “Markup Compatibility and Extensibility”. Producers editing relationships based on this version of the relationship markup specification shall not preserve any ignored content, regardless of the presence of any preservation attributes as defined in Part 5: “Markup Compatibility and Extensibility”.	8.3.5			×	×
M1.32	If a fragment identifier is allowed in the Target attribute of the Relationship element, a package implementer shall not resolve the URI to a scope less than an entire part.	8.3.3.2	×			
M1.33	A Unicode string representing a URI can be passed to the producer or consumer. The producing or consuming application shall convert the Unicode string to a URI. If the URI is a relative reference, the application shall resolve it using the base URI of the part, which is expressed using the pack scheme, to the URI of the referenced part.	Annex A			×	×
M1.34	If a consumer converts the URI back into an IRI, the conversion shall be performed as specified in §3.2 of RFC 3987.	A.2				×

Table H–2. Package model optional requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O1.1	The package implementer might allow a growth hint to be provided by a producer.	8.1, 8.1.3	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O1.2	Format designers might restrict the usage of parameters for content types.	8.1.2		×		
O1.3	The package implementer might ignore the growth hint or adhere only loosely to it when specifying the physical mapping.	8.1.3	×			
O1.4	If the format designer permits it, parts can contain Unicode strings representing references to other parts. If allowed by the format designer, format producers can create such parts and format consumers shall consume them.	8.2.1		×	×	×
O1.5	The package implementer might allow a TargetMode to be provided by a producer.	8.3.3.2	×			
O1.6	A format designer might allow fragment identifiers in the value of the Target attribute of the Relationship element.	8.3.3.2		×		
O1.7	Producers might generate relationship markup that uses the versioning and extensibility mechanisms defined in Part 5: “Markup Compatibility and Extensibility” to incorporate elements and attributes drawn from other XML namespaces.	8.3.5			×	

H.2 Physical Packages

Table H–3. Physical packages conformance requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M2.1	The Content Types stream shall not be mapped to a part by the package implementer.	9.1.2.1	×[A]			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M2.2	The package implementer shall define a physical package format with a mapping for the required components package, part name, part content type and part contents.	9.1.1	×			
M2.3	The package implementer shall define a format mapping with a mechanism for associating content types with parts.	9.1.2.1	×			
M2.4	The package implementer shall require that the Content Types stream contain one of the following for every part in the package: One matching Default element One matching Override element Both a matching Default element and a matching Override element, in which case the Override element takes precedence.	9.1.2.2	×[A]			
M2.5	The package implementer shall require that there not be more than one Default element for any given extension, and there not be more than one Override element for any given part name.	9.1.2.2	×[A]			
M2.6	The package implementer shall require a non-empty extension in a Default element. The package implementer shall require a content type in a Default element and the format designer shall specify the content type.	9.1.2.2.2	×[A]	×[A]		
M2.7	The package implementer shall require a content type and the format designer shall specify the content type in an Override element. The package implementer shall require a part name.	9.1.2.2.3	×[A]	×[A]		

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M2.8	When adding a new part to a package, the package implementer shall ensure that a content type for that part is specified in the Content Types stream; the package implementer shall perform the steps described in §9.1.2.3.	9.1.2.3	×[A]			
M2.9	To get the content type of a part, the package implementer shall perform the steps described in §9.1.2.4.	9.1.2.4	×[A]			
M2.10	The package implementer shall not use the versioning and extensibility mechanisms defined in Part 5: "Markup Compatibility and Extensibility" to incorporate elements and attributes drawn from other XML-namespaces into the Content Types stream markup.	9.1.2.5	×[A]			
M2.11	The package implementer shall not mix interleaving and non-interleaving for an individual part.	9.1.4	×[B]			
M2.12	The package implementer shall compare prefix names as case-insensitive ASCII strings.	9.1.3.1	×			
M2.13	The package implementer shall compare suffix names as case-insensitive ASCII strings.	9.1.3.1	×[B]			
M2.14	The package implementer shall not allow packages that contain equivalent logical item names.	9.1.3.1	×			
M2.15	The package implementer shall not allow packages that contain logical items with equivalent prefix names and with equal piece numbers, where piece numbers are treated as integer decimal values.	9.1.3.1	×[B]			
M2.16	The package implementer shall not map logical items to parts if the logical item names violate the part naming rules.	9.1.3.4	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M2.17	The package implementer shall consider naming collisions within the set of part names mapped from logical item names to be an error.	9.1.3.4	×			
M2.18	When interleaved, a package implementer shall represent a part as one or more pieces, using the method described in §9.1.4.	9.2.1	×[B]			

Notes:

A: Only relevant if using the content type mapping strategy specified in the Open Packaging Conventions.

B: Only relevant if supporting the interleaving strategy specified in the Open Packaging Conventions.

Table H–4. Physical packages recommendations

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
S2.1	Some physical package formats have a native mechanism for representing content types. For such packages, the package implementer should use the native mechanism to map the content type for a part.	9.1.2.1	×			
S2.2	If no native method of mapping a content type to a part exists, the package implementer should include a specially-named XML stream in the package called the Content Types stream	9.1.2.1	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
S2.3	If the package is intended for streaming consumption: The package implementer should not allow Default elements; as a consequence, there should be one Override element for each part in the package. The format producer should write the Override elements to the package so they appear before the parts to which they correspond, or in close proximity to the part to which they correspond.	9.1.2.2	×[A]		×[A]	
S2.4	The package implementer should use the mechanism described in this Open Packaging specification to allow interleaving when mapping to the physical package for layout scenarios that support streaming consumption.	9.1.4	×[B]			
S2.5	The package implementer should store pieces in their natural order for optimal efficiency.	9.1.4	×[B]			

Notes:

A: Only relevant if using the content type mapping strategy specified in the Open Packaging Conventions.

B: Only relevant if supporting the interleaving strategy specified in the Open Packaging Conventions.

Table H–5. Physical packages optional requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O2.1	The format designer specifies whether that format might use interleaving.	9.1.4		×		

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O2.2	Optional. The package implementer might provide a physical mapping for a growth hint that might be specified by a producer.	9.1.1	×			
O2.3	Package implementers might use the common mapping solutions defined in this Open Packaging specification.	9.1	×			
O2.4	Package producers can use pre-defined Default elements to reduce the number of Override elements on a part, but are not required to do so.	9.1.2.2			×[A]	
O2.5	The package implementer can define Default content type mappings even though no parts use them.	9.1.2.2	×[A]			
O2.6	The package implementer might create a physical package containing interleaved parts and non-interleaved parts.	9.1.4	×			
O2.7	The package implementer might allow a package that contains logical item names and complete sequences of logical item names that cannot be mapped to a part name because the logical item name does not follow the part naming grammar or the logical item does not have an associated content type.	9.1.3.4	×[B]			

Notes:

A: Only relevant if using the content type mapping strategy specified in the Open Packaging Conventions.

B: Only relevant if supporting the interleaving strategy specified in the Open Packaging Conventions.

H.3 ZIP Physical Mapping

The requirements in Table H–6, Table H–7, and

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
S3.2	If a growth hint is used for an interleaved part, the package implementer should store the Extra field containing the growth hint padding with the item that represents the first piece of the part.	10.2.7	×			

Table J–8 are only relevant when mapping to the ZIP physical package format.

Table H–6. ZIP physical mapping conformance requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M3.1	A package implementer shall store a non-interleaved part as a single ZIP item.	9.2.1	×			
M3.2	ZIP item names are case-sensitive ASCII strings. Package implementers shall create ZIP item names that conform to ZIP archive file name grammar.	9.2.2	×			
M3.3	Package implementers shall create item names that are unique within a given archive.	9.2.2	×			
M3.4	To map part names to ZIP item names the package implementer shall perform, in order, the steps described in §9.2.3.	9.2.3	×			
M3.5	The package implementer shall not map a logical item name or complete sequence of logical item names sharing a common prefix to a part name if the logical item prefix has no corresponding content type.	9.2.3	×			
M3.6	To map ZIP item names to part names, the package implementer shall perform, in order, the steps described in §9.2.4.	9.2.4	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M3.7	The package implementer shall map all ZIP items to parts except MS-DOSZIP items, as defined in the ZIP specification, that are not MS-DOS files.	9.2.5	×			
M3.8	The package implementer shall map all ZIP items to parts except MS-DOSZIP items, as defined in the ZIP specification, that are not MS-DOS files. [M3.7] [*Note:* The ZIP specification specifies that ZIP items recognized as MS-DOS files are those with a "version made by" field and an "external file attributes" field in the "file header" record in the central directory that have a value of 0. *end note]* In ZIP archives, the package implementer shall not exceed 65,535 bytes for the combined length of the item name, Extra field, and Comment fields.	9.2.5	×			
M3.9	ZIP-based packages shall not include encryption as described in the ZIP specification. Package implementers shall enforce this restriction.	9.2.5	×			
M3.10	Package implementers shall store content type data in an item(s) mapped to the logical item name with the prefix_name equal to "/[Content_Types].xml" or in the interleaved case to the complete sequence of logical item names with that prefix_name.	9.2.6	×			
M3.11	Package implementers shall not map logical item name(s) mapped to the Content Types stream in a ZIP archive to a part name.	9.2.6	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M3.13	Several substantial conditions that represent a package unfit for streaming consumption may be detected mid-processing by a streaming package implementer, described in §9.2.8. When any of these conditions are detected, the streaming package implementer shall generate an error, regardless of any processing that has already taken place. Package implementers shall not generate a package containing any of these conditions when generating a package intended for streaming consumption.	9.2.8	×			
M3.14	For a ZIP archive to be a valid physical layer for a package, the package implementer shall ensure that the ZIP archive holds equal values in the appropriate fields of every File Header within the Central Directory and the corresponding Local File Header and Data Descriptor pair.	Annex C	×			
M3.15	During consumption of a package, a "Yes" value for a field in a table in Annex C indicates a package implementer shall support reading the ZIP archive containing this record or field, however, support may mean ignoring.	Annex C	×			
M3.16	During production of a package, a “Yes” value for a field in a table in Annex C indicates that the package implementer shall write out this record or field.	Annex C	×			
M3.17	A “No” value for a field in a table in Annex C indicates the package implementer shall not use this record or field during consumption or production of packages.	Annex C	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M3.18	A “Partially, details below” value for a record in a table in Annex C indicates that the record contains fields that might not be supported by package implementers during production or consumption. See the details in the corresponding table to determine requirements.	Annex C	×			
M3.19	The value “Only used when needed” associated with a record in a table in Annex C indicates that the package implementer shall use the record only when needed to store data in the ZIP archive.	Annex C	×			
M3.20	The value “Only used when needed” associated with a record in a table in Annex C indicates that the package implementer shall use the record only when needed to store data in the ZIP archive.	Annex C	×			
M3.21	The package implementer shall ensure that all 64-bit stream record sizes and offsets have the high-order bit = 0.	Annex C	×			

Notes:

A: Only relevant if supporting the interleaving strategy specified in the Open Packaging Conventions.

Table H–7. ZIP physical mapping recommendations

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
S3.1	Package implementers should restrict part naming to accommodate file system limitations when naming parts to be stored as ZIP items.	9.2.5	×			
S3.2	If a growth hint is used for an interleaved part, the package implementer should store the Extra field containing the growth hint padding with the item that represents the first piece of the part.	9.2.7	×			

Table H–8. ZIP physical mapping optional requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O3.1	A package implementer might intentionally order the sequence of ZIP items in the archive to enable an efficient organization of the part data in order to achieve correct and optimal interleaving.	9.2.1	×			
O3.2	An “Optional” value for a record in a table in Annex C indicates that package implementers might write this record during production.	Annex C	×			

H.4 Core Properties

The requirements in Table H–9 are only relevant if using the core properties feature.

Table H–9. Core properties conformance requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M4.1	The format designer shall specify and the format producer shall create at most one core properties relationship for a package. A format consumer shall consider more than one core properties relationship for a package to be an error. If present, the relationship shall target the Core Properties part.	10.2		×	×	×
M4.2	The format designer shall not specify and the format producer shall not create Core Properties that use the Markup Compatibility namespace as defined in Annex F, “Standard Namespaces and Content Types”. A format consumer shall consider the use of the Markup Compatibility namespace to be an error.	10.3		×	×	×

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M4.3	Producers shall not create a document element that contains refinements to the Dublin Core elements, except for the two specified in the schema: <dcterms:created> and <dcterms:modified> Consumers shall consider a document element that violates this constraint to be an error.	10.4			×	×
M4.4	Producers shall not create a document element that contains the xml:lang attribute. Consumers shall consider a document element that violates this constraint to be an error.	10.4			×	×
M4.5	Producers shall not create a document element that contains the xsi:type attribute, except for a <dcterms:created> or <dcterms:modified> element where the xsi:type attribute shall be present and shall hold the value dcterms:W3CDTF, where `dcterms` is the namespace prefix of the Dublin Core namespace. Consumers shall consider a document element that violates this constraint to be an error.	10.4			×	×

H.5 Thumbnail

The requirements in Table H–10 and Table H–11 are only relevant if using the thumbnail feature.

Table H–10. Thumbnail conformance requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M5.1	The format designer shall specify thumbnail parts that are identified by either a part relationship or a package relationship. The producer shall build the package accordingly.	11.1		×	×	

Table H–11. Thumbnail optional requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O5.1	The format designer might allow images, called thumbnails, to be used to help end-users identify parts of a package or a package as a whole. These images can be generated by the producer and stored as parts.	11		×	×	

H.6 Digital Signatures

The requirements in Table H–12, Table H–13, and Table H–14 are only relevant if using the digital signatures feature.

Table H–12. Digital Signatures conformance requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M6.1	The package implementer shall include only one Digital Signature Origin part in a package and it shall be targeted from the package root using the well-defined relationship type specified in Annex F, “Standard Namespaces and Content Types”.	12.2.1	×			
M6.2	When creating the first Digital Signature XML Signature part, the package implementer shall create the Digital Signature Origin part, if it does not exist, in order to specify a relationship to that Digital Signature XML Signature part.	12.2.1	×			
M6.3	The producer shall create Digital Signature XML Signature parts that have a relationship from the Digital Signature Origin part and the consumer shall use that relationship to locate signature information within the package.	12.2.1			×	×

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M6.4	If the certificate is represented as a separate part within the package, the producer shall target that certificate from the appropriate Digital Signature XML Signature part by a Digital Signature Certificate relationship as specified in Annex F, “Standard Namespaces and Content Types” and the consumer shall use that relationship to locate the certificate.	12.2.3			×	×
M6.5	The producer shall create Reference elements within a SignedInfo element that reference elements within the same Signature element. The consumer shall consider Reference elements within a SignedInfo element that reference any resources outside the same Signature element to be in error.	12.2.4.1			×	×
M6.6	The producer shall not create a reference to a package-specific Object element that contains a transform other than a canonicalization transform. The consumer shall consider a reference to a package-specific Object element that contains a transform other than a canonical transform to be an error.	12.2.4.1			×	×
M6.7	The producer shall create one and only one package-specific Object element in the Signature element. The consumer shall consider zero or more than one package-specific Object element in the Signature element to be an error.	12.2.4.1			×	×

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M6.8	The producer shall create package-specific Object elements that contain exactly one Manifest element and exactly one SignatureProperties element. [*Note:* This SignatureProperties element can contain multiple SignatureProperty elements. *end note*] The consumer shall consider package-specific Object elements that contain other types of elements to be an error.	12.2.4.1			×	×
M6.9	The producer shall create Reference elements within a Manifest element that reference with their URI attribute only parts within the package. The consumer shall consider Reference elements within a Manifest element that reference resources outside the package to be an error.	12.2.4.1			×	×
M6.10	The producer shall create relative references to the local parts that have query components that specifies the part content type as described in §12.2.4.6. The relative reference excluding the query component shall conform to the part name grammar. The consumer shall consider a relative reference to a local part that has a query component that incorrectly specifies the part content type to be an error.	12.2.4.1			×	×

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M6.11	The producer shall create Reference elements with a query component that specifies the content type that matches the content type of the referenced part. The consumer shall consider signature validation to fail if the part content type compared in a case-sensitive manner to the content type specified in the query component of the part reference does not match.	12.2.4.1			×	×
M6.12	The producer shall not create Reference elements within a Manifest element that contain transforms other than the canonicalization transform and relationships transform. The consumer shall consider Reference elements within a Manifest element that contain transforms other than the canonicalization transform and relationships transform to be in error.	12.2.4.1			×	×
M6.13	A producer that uses an optional relationships transform shall follow it by a canonicalization transform. The consumer shall consider any relationships transform that is not followed by a canonicalization transform to be an error.	12.2.4.1			×	×

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M6.14	The producer shall create exactly one SignatureProperty element with the Id attribute value set to `idSignatureTime`. The Target attribute value of this element shall be either empty or contain a fragment reference to the value of the Id attribute of the root Signature element. A SignatureProperty element shall contain exactly one SignatureTime child element. The consumer shall consider a SignatureProperty element that does not contain a SignatureTime element or whose Target attribute value is not empty or does not contain a fragment reference the Id attribute of the ancestor Signature element to be in error.	12.2.4.1			×	×
M6.15	The producer shall create a Signature element that contains exactly one local-data, package-specific Object element and zero or more application-specific Object elements. If a Signature element violates this constraint, a consumer shall consider this to be an error.	12.2.4.2			×	×
M6.16	The producer shall create a SignedInfo element that contains exactly one reference to the package-specific Object element. The consumer shall consider it an error if a SignedInfo element does not contain a reference to the package-specific Object element.	12.2.4.3			×	×
M6.17	Producers shall support DSA and RSA algorithms to produce signatures. Consumers shall support DSA and RSA algorithms to validate signatures.	12.2.4.5			×	×

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M6.18	The producer shall create a Reference element within a Manifest element with a URI attribute and that attribute shall contain a part name, without a fragment identifier. The consumer shall consider a Reference element with a URI attribute that does not contain a part name to be an error.	12.2.4.6			×	×
M6.19	The following transforms shall be supported by producers and consumers of packages with digital signatures: • XML Canonicalization (c14n) • XML Canonicalization with Comments (c14n with comments) • Relationships transform (package-specific) Consumers validating signed packages shall fail the validation if other transforms are encountered. Relationships transforms shall only be supported by producers and consumers when the Transform element is a descendant element of a Manifest element	12.2.4.7			×	×
M6.20	Producers shall create application-specific Object elements that contain XML-compliant data; consumers shall treat data that is not XML-compliant as an error.	12.2.4.14			×	×
M6.21	Producers and consumers shall use the certificate embedded in the Digital Signature XML Signature part when it is specified.	12.2.4.15			×	×

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M6.22	The producer shall not create a Manifest element that references any data outside of the package. The consumer shall consider a Manifest element that references data outside of the package to be in error.	12.2.4.18			×	×
M6.23	The producer shall create a data/time format that conforms to the syntax described in the W3C Note "Date and Time Formats". The consumer shall consider a format that does not conform to the syntax described in that WC3 note to be in error.	12.2.4.22			×	×
M6.24	The producer shall create a value that conforms to the format specified in the Format element. The consumer shall consider a value that does not conform to that format to be in error.	12.2.4.23			×	×
M6.25	To sign a subset of relationships, the producer shall use the package-specific relationships transform. The consumer shall use the package-specific relationships transform to validate the signature when a subset of relationships are signed.	12.2.4.25			×	×
M6.26	Producers shall specify a canonicalization transform immediately following a relationships transform and consumers that encounter a relationships transform that is not immediately followed by a canonicalization transform shall generate an error.	12.2.4.25			×	×

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M6.27	When applying a relationships transform for digital signatures, the package implementer shall remove all Relationship elements that do not have eitheran Id value that matches any SourceId valueor a Type value that matches any SourceType value, among the SourceId and SourceType values specified in the transform definition. Producers and consumers shall compare values as case-sensitive Unicode strings.	12.2.4.26			×	×
M6.28	When signing Object element data, package implementers shall follow the generic reference creation algorithm described in §3.1 of the W3C Recommendation “XML-Signature Syntax and Processing”.	12.4	×			
M6.29	When validating digital signatures, consumers shall verify the content type and the digest contained in each Reference descendant element of the SignedInfo element, and validate the signature calculated using the SignedInfo element.	12.5				×
M6.30	The package implementer shall compare the generated digest value against the DigestValue element in the Reference element of the SignedInfo element. Package implementers shall consider references invalid if there is any mismatch.	12.5	×			
M6.31	Streaming consumers that maintain signatures shall be able to cache the parts necessary for detecting and processing signatures.	12.5.1				×

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M6.32	The package implementer shall not use the Markup Compatibility namespace, as specified in Annex F, "Standard Namespaces and Content Types," within the package-specific Object element. The package implementer shall consider the use of the Markup Compatibility namespace within the package-specific Object element to be an error.	12.6.2	×			
M6.33	If an application allows for a single part to contain information that might not be fully understood by all implementations, then the format designer shall carefully design the signing and verification policies to account for the possibility of different implementations being used for each action in the sequence of content creation, content signing, and signature verification. Producers and consumers shall account for this possibility in their signing and verification processing.	12.6.2		×	×	×
M6.34	The following canonicalization methods shall be supported by producers and consumers of packages with digital signatures: XML Canonicalization (c14n) XML Canonicalization with Comments (c14n with comments) Consumers validating signed packages shall fail the validation if other canonicalization methods are encountered.	12.2.4.4			×	×
M6.35	A producer shall not specify more than one relationship transform for a particular relationships part. A consumer shall treat the presence of more than one relationship transform for a particular relationships part as an error.	12.2.4.25			×	×

Table H–13. Digital signatures recommendations

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
S6.1	The producer should not create any content in the Digital Signature Origin part itself.	12.2.1			×	
S6.2	Producers generating digital signatures should not create Digital Signature Certificate parts that are not the target of at least one Digital Signature Certificate relationship from a Digital Signature XML Signature part. In addition, producers should remove a Digital Signature Certificate part if removing the last Digital Signature XML Signature part that has a Digital Signature Certificate relationship to it.	12.2.3			×	
S6.3	For digital signatures, a producer should apply a canonicalization transform to the SignedInfo element when it generates it, and a consumer should apply the canonicalization transform to the SignedInfo element when validating it.	12.2.4.4			×	×
S6.4	Producers and consumers should also use canonicalization transforms for references to parts that hold XML documents.	12.2.4.4			×	×
S6.5	The producer should only create Reference elements within a SignedInfo element that reference an Object element.	12.2.4.1			×	

Table H–14. Digital signatures optional requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O6.1	Format designers might allow a package to include digital signatures to enable consumers to validate the integrity of the contents. The producer might include the digital signature when allowed by the format designer.	12		×	×	

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O6.2	If there are no Digital Signature XML Signature parts in the package, the Digital Signature Origin part is optional.	12.2.1			×	
O6.4	The producer might create zero or more Digital Signature XML Signature parts in a package.	12.2.2			×	
O6.5	Alternatively, the producer might store the certificate as a separate part in the package, might embed it within the Digital Signature XML Signature part itself, or might not include it in the package if certificate data is known or can be obtained from a local or remote certificate store.	12.2.3			×	
O6.6	The producer might sign the part holding the certificate.	12.2.3			×	
O6.7	Producers might share Digital Signature Certificate parts by using the same certificate to create more than one signature.	12.2.3			×	
O6.8	The format designer might permit one or more application-specific Object elements. If allowed by the format designer, format producers can create one or more application-specific Object elements.	12.2.4.14		×	×	
O6.9	Format designers and producers might not apply package-specific restrictions regarding URIs and Transform elements to application-specific Object element.	12.2.4.14		×	×	
O6.10	Format designers might permit producers to sign individual relationships in a package or the Relationships part as a whole.	12.2.4.25		×	×	

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O6.11	The package implementer might create relationships XML that contains content from several namespaces, along with versioning instructions as defined in Part 5: “Markup Compatibility and Extensibility”.	12.2.4.26	×			
O6.12	Format designers might specify an application-specific package part format that allows for the embedding of versioned or extended content that might not be fully understood by all present and future implementations. Producers might create such embedded versioned or extended content and consumers might encounter such content.	12.6.2		×	×	×

H.7 Pack URI

Table H–15. Pack URI conformance requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M7.1	The authority component contains an embedded URI that points to a package. The package implementer shall create an embedded URI that meets the requirements defined in RFC 3986 for a valid URI.	B.1	×			
M7.2	The optional path component identifies a particular part within the package. The package implementer shall only create path components that conform to the part naming rules. When the path component is missing, the resource identified by the pack URI is the package as a whole.	B.1	×			

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
M7.3	The package implementer shall consider pack URIs equivalent if: The scheme components are octet-by-octet identical after they are both converted to lowercase; *and* The URIs, decoded as described in §B.2 from the authority components are equivalent (the equivalency rules *by* scheme, as per RFC 3986); and The path components are equivalent when compared as case-insensitive ASCII strings.	B.4	×			
M7.4	The package implementer shall not create an authority component with an unescaped colon (:) character.	B.1	×			

Table H–16. Pack URI optional requirements

ID	Rule	Reference	Package Implementer	Format Designer	Format Producer	Format Consumer
O7.1	Consumer applications, based on the obsolete URI specification RFC 2396, might tolerate the presence of an unescaped colon character in an authority component.	B.1				×

Office Open XML

Part 3: Primer

December 2006

Table of Contents

Foreword

This multi-part Standard deals with Office Open XML Format-related technology, and consists of the following parts:

- Part 1: "Fundamentals"
- Part 2: "Open Packaging Conventions"
- **Part 3: "Primer"(this document)**
- Part 4: "Markup Language Reference"
- Part 5: "Markup Compatibility and Extensibility"

Introduction

This Part is one piece of a specification that describes a family of XML schemas, collectively called *Office Open XML*, which define the XML vocabularies for word-processing, spreadsheet, and presentation documents, as well as the packaging of documents that conform to these schemas.

The goal is to enable the implementation of the Office Open XML formats by the widest set of tools and platforms, fostering interoperability across office productivity applications and line-of-business systems, as well as to support and strengthen document archival and preservation, all in a way that is fully compatible with the large existing investments in Microsoft Office documents.

1. Scope

This Part contains a detailed introduction to the following Office Open XML topics:

- WordprocessingML
- SpreadsheetML
- PresentationML
- DrawingML
- VML
- Various shared MLs

The organization of this Part is much the same as its corresponding reference Part, Part 4, and is intended as a gentle introduction to Part 4.

2. Introduction to WordprocessingML

This clause is informative.

This clause contains a detailed introduction to the structure of a WordprocessingML document.

2.1 Stories

A WordprocessingML document is composed of a collection of stories. Each *story* represents a distinct region of text within the document. The following kinds of region exist: comment (§2.14.5), endnote (§2.12.2), footer (§2.11.2), footnote (§2.12.1), frame, glossary document (§2.13), header (§2.11.1), main story (§2.2), subdocument (§2.18.2), and text box (§2.18.1).

With one exception (a glossary document), all stories in a document utilize a common set of properties that determine the presentation of the contents of each story. These properties include font information, style definitions, numbering definitions, and document settings.

2.2 Basic Document Structure

The main document story of the simplest WordprocessingML document consists of the following XML elements:

- document — The root element for a WordprocessingML's main document part, which defines the main document story.
- body — The container for the collection of block-level structures that comprise the main story.
- p — A paragraph.
- r — A run.
- t — A range of text.

A *run* is a region of text in a story with a common set of properties. The text in a WordprocessingML document must be contained within one or more runs. A *paragraph* is a collection of one or more runs that is displayed as a unit. A run must be contained within a paragraph.

Consider the following Main Document XML for a simple WordprocessingML document:

```
<?xml version="1.0"?>
<w:document xmlns:w="…">
  <w:body>
    <w:p>
      <w:r>
        <w:t>Hello, world.</w:t>
      </w:r>
    </w:p>
  </w:body>
</w:document>
```

2.3 Main Document Story

The contents of the main document story—the only story that is required in a valid WordprocessingML document—are encapsulated within the body element. The content of the main document body is a collection of block-level structures, which are those WordprocessingML elements that can contain and/or be sibling elements with a WordprocessingML paragraph.

Within the document body, the valid set of block level content is:

- Paragraphs
- Tables
- Custom markup (custom XML, structured document tags)
- Section properties
- Annotations (comments, revision markers, range permission markers)
- Alternate format chunks

Each of these block-level content constructs (the 'building blocks' of WordprocessingML) is defined in the following subclauses.

2.3.1 Document Backgrounds

As well as containing a body, a document element can also contain the definition of the document's background via the background element and its contents. This background applies to all printed pages within this document. A document background in WordprocessingML can have a single color, as well as the application of various drawing effects such as color gradient or pattern, and a tiled or stretched image. All background information in a WordprocessingML document is stored using the Vector Markup Language (VML) syntax. The single exception to this is the background color, which is stored natively in WordprocessingML using the bgColor attribute.

Consider a simple background in WordprocessingML, which consists of a single color with a gradient fill applied:

```
<w:background w:bgColor="5C83B4">
  <v:background id="_x0000_s1025" o:bwmode="white" fillcolor="#5c83b4
    [3204] o:targetscreensize="800,600">
    <v:fill color2="fill darken(118) method="linear sigma" focus="100%"
      type="gradient"/>
  </v:background>
</w:bgPict>
```

The background consists of two components: a background fill color of RGB value 5C83B4, and the background gradient stored as a VML transformation.

2.4 Paragraphs and Rich Formatting

2.4.1 Paragraphs

The most basic unit of block-level content within a WordprocessingML document, *paragraphs* are stored using the p element. A *paragraph* defines a distinct division of content that begins on a new line. A paragraph can contain three pieces of information: optional paragraph properties, inline content (typically runs), and a set of optional revision IDs used to compare the content of two documents.

Consider the paragraph fragment "*The quick brown fox jumped …*" which is centered on a paragraph. As all the text in the paragraph is emphasized using italics, in the XML, the contents of the paragraph will have the justify-center property, and each run within the paragraph (as well as the run properties for the paragraph mark) stores the italics property; for example:

```
<w:p>
  <w:pPr>
    <w:jc w:val="center"/>
    <w:rPr>
      <w:i/>
    </w:rPr>
  </w:pPr>
  <w:r>
    <w:rPr>
      <w:i/>
    </w:rPr>
    <w:t>The quick brown fox jumped…</w:t>
  </w:r>
</w:p>
```

Notice that each run specifies the character formatting information for its contents, and the paragraph specifies the paragraph level formatting (the center-justification). It is also notable that since leading and trailing whitespace is not normally significant in XML, some runs require a designating specifying that their whitespace is significant via the xml:space element.

A paragraph's properties are specified via the pPr element. Some examples of paragraph properties are alignment, border, hyphenation override, indentation, line spacing, shading, text direction, and widow/orphan control.

It should also be noted that a pPr element may contain a set of run properties within a rPr element – these properties are applied to the run which contains the glyph which represents the paragraph mark and not the entire paragraph.

2.4.2 Runs

The next level of the document hierarchy is the *run*, which defines a region of text with a common set of properties, represented by the r element. An r element allows the producer to combine breaks, styles, or formatting properties, applying the same information to all the parts of the run.

Just as a paragraph can have properties, so too can a run. All of the elements inside an r element have their properties controlled by a corresponding optional rPr run properties element, which must be the first child of the r element. In turn, the rPr element is a container for a set of property elements that are applied to the rest of the children of the r element. The elements inside the rPr container element allow the consumer to control whether the text in the following t elements is bold, underlined, or visible, for example. Some examples of run properties are bold, border, character style, color, font, font size, italic, kerning, disable spelling/grammar check, shading, small caps, strikethrough, text direction, and underline.

Consider the following run within a WordprocessingML document:

```
<w:r>
  <w:rPr>
    <w:b/>
    <w:i/>
  </w:rPr>
  <w:t>quick</w:t>
</w:r>
```

The run specifies two formatting properties in its run contents: bold and italic. These properties are therefore applied to all content within this run.

A producer can break a run into an arbitrary number of smaller runs, provided each smaller run uses the same set of properties, without changing the content of the document.

Consider the content "only one word is emphasized" in a WordprocessingML document. An efficient producer could choose to output this content using two runs, as follows:

```
<w:r>
  <w:t xml:space="preserve">only one word is </w:t>
</w:r>
```

```
<w:r>
  <w:rPr>
    <w:i/>
  <w:rPr>
  <w:t>emphasized</w:t>
</w:r>
```

However, a less efficient producer might use four runs, as follows:

```
<w:r>
  <w:t>only one</w:t>
</w:r>
<w:r>
  <w:t xml:space="preserve"> word is </w:t>
</w:r>
<w:r>
  <w:rPr>
    <w:i/>
  <w:rPr>
  <w:t>empha</w:t>
</w:r>
<w:r>
  <w:rPr>
    <w:i/>
  <w:rPr>
  <w:t>sized</w:t>
</w:r>
```

Although the latter example uses four runs rather than two, the net run information applied to each region of text is identical, and both are equally valid.

Of course, a run might need to be broken. For example, the properties of only some the text in that run are changed, requiring the changed part to be put into its own run. Another example involves the insertion of some sort of marker into the middle of an existing run. That requires the run be broken into two with the marker inserted between them.

The following run contains two sentences:

```
<w:r>
  <w:t>Hello, world. How are you, today?</w:t>
</w:r>
```

If the first two words are bolded in these sentences, the run will need to be broken into two runs in order to store the formatting, as follows:

```
<w:r>
  <w:rPr>
    <w:b/>
  </w:rPr>
  <w:t xml:space="preserve">Hello, world. </w:t>
</w:r>
<w:r>
  <w:t>How are you, today?</w:t>
</w:r>
```

Apart from text, a run can also contain numerous kinds of textual content (§2.4.3) A run can also contain a set of revision IDs used for document "merge and compare".

2.4.3 Run Content

The lowest level of this hierarchy is *run content*, that content that can be stored within a single run in a document. In WordprocessingML, the types of run content include:

- Text
- Deleted text
- Soft line breaks
- Field codes
- Deleted field codes
- Footnote/endnote reference marks
- Simple fields
- Page numbers
- Tabs
- Ruby text
- DrawingML content
- Embedded objects
- Pictures

2.4.3.1 Text

The most common run content is the t element, which is the container for the text that makes up the document's content. A t element can contain an arbitrary amount of text, up to and including the entire document's contents. However, typically, long runs of text are broken up into paragraphs and strings of text having different formats, or are interrupted by line breaks, graphics, tables, and other items. A t element must be enclosed within an r element; i.e., a run of text. An r element can contain multiple t elements, interspersed among other elements.

Aside from the t element, there are three types of text in WordprocessingML:

- delText - Deleted text
- instrText - Field codes

- delInstrText - Deleted field codes

These four types of text are defined using unique elements in WordprocessingML so that simple consumers can determine the text of the document simply by grabbing the contents of the t node, without needing to check where revisions start and end, etc. to determine the state of the text contents.

It is also notable that these are the only elements in a WordprocessingML document's main document part that can contain a XML text node.

2.4.4 Formatting Property Values

Most of the children of an rPr or pPr element have a single val attribute that is limited to a specific set of values. For example, the b (bold) element causes the text that follows it to be bold when the b element has a val attribute with value on. If the val attribute isn't present for the b element, it defaults to "on". Therefore, <w:b/> is equivalent to <w:b w:val="on"/>.

Aside from the default values, which are documented with each element, this is particularly important when specifying the difference between omitting a formatting property and explicitly turning it off.

For example, consider the following run:

```
<w:r>
  <w:rPr>
    <w:b w:val="off"/>
  </w:rPr>
  <w:t xml:space="preserve">Hello, world. </w:t>
</w:r>
```

This run explicitly declares that the bold property is turned off for this text, as opposed to the following run:

```
<w:r>
  <w:t xml:space="preserve">Hello, world. </w:t>
</w:r>
```

This run says nothing about the bold property. This distinction is particularly important when dealing with content that is formatting using styles - if the content was not contained in a styled paragraph, both would be identical. However, in the case where the paragraph is styled, the former would never be bold regardless of the style information, whereas the latter would express the bold property as set by the style, since it's omission of the bold property means "whatever the underlying formatting is".

Some elements have val attributes that offer a richer set of choices than on and off; the u (underline) element is one such element. In this case, the same rules apply, the omission of the property simply means use the underlying properties.

2.5 Tables

Another type of block-level content in WordprocessingML, A *table* is a set of paragraphs (and other block-level content) arranged in *rows* and *columns*.

2.5.1 Introduction

Tables in WordprocessingML are defined via the tbl element, which is analogous to the HTML `<table>` tag. The table element specifies the location of a table present in the document.

A tbl element has two elements that define its properties: tblPr, which defines the set of table-wide properties (such as style and width), and tblGrid, which defines the grid layout of the table. A tbl element can also contain an arbitrary non-zero number of rows, where each row is specified with a tr element. Each tr element can contain an arbitrary non-zero number of cells, where each cell is specified with a tc element.

Consider an empty one-cell table (i.e.,; a table with one row, one column) and 1 point borders on all sides:

This table is represented by the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblW w:w="5000" w:type="pct"/>
    <w:tblBorders>
      <w:top w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:left w:val="single" w:sz="4 w:space="0" w:color="auto"/>
      <w:bottom w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:right w:val="single" w:sz="4" w:space="0" w:color="auto"/>
    </w:tblBorders>
  </w:tblPr>
  <w:tblGrid>
    <w:gridCol w:w="10296"/>
  </w:tblGrid>
  <w:tr>
    <w:tc>
      <w:tcPr>
        <w:tcW w:w="0" w:type="auto"/>
      </w:tcPr>
      <w:p/>
    </w:tc>
  </w:tr>
</w:tbl>
```

This table specifies table-wide properties of 100% of page width (tblW's type attribute specifies how the width value in the w attribute shall be interpreted—pct specifies a measurement of fiftieths of a percent) and the set of table borders (tblBorders), the table grid which defines a set of shared vertical edges within the table (discussed later), and a single row.

2.5.2 Table Properties

The tblPr element defines table-wide properties, properties which are applied to each row and cell in the table. The complete set of table-wide properties can be found on the definition for the tblPr element.

Consider the following simple WordprocessingML table:

This table defines outside and inside table borders, etc; and is set to 100% of page width - both table-wide properties. The resulting table is represented by the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblW w:w="0" w:type="auto"/>
    <w:tblBorders>
      <w:top w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:left w:val="single" w:sz="4 w:space="0" w:color="auto"/>
      <w:bottom w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:right w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:insideH w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:insideV w:val="single" w:sz="4" w:space="0" w:color="auto"/>
    </w:tblBorders>
  </w:tblPr>
  <w:tblGrid>
    ...
  </w:tblGrid>
  <w:tr>
    ...
  </w:tr>
</w:tbl>
```

In this example, the tblW element defines the total width of the table, which, in this case, is set to a type of auto, which specifies that the table should be sized to fit its contents. The tblBorders element specifies each of the table's borders, and specifies a one point border on the top, left, bottom, right and inside horizontal and vertical border. The table-wide properties can be overwritten on an individual row basis by specifying table property overrides within the table row properties.

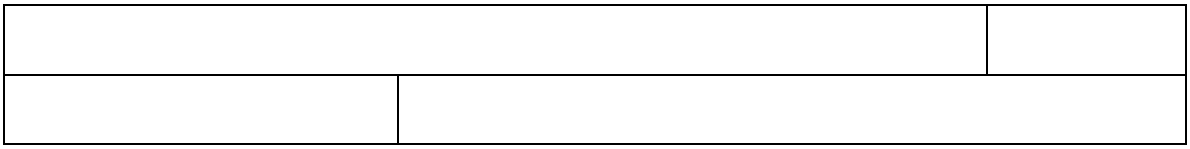
2.5.3 Table Grid

The tblGrid element defines the *grid* for the table. All columns in the table (including the space before and after a row) reference this grid. Each gridCol defines a single grid column within the table's layout, which is used to define the presence of a vertical line within the table. A tblGrid element can contain an arbitrary number of gridCol elements, where each gridCol element represents one grid column in the table and defines a single grid entry. When cells are laid out within this table, as discussed below, all cells will be forced to snap the shared column edges defined by this grid.

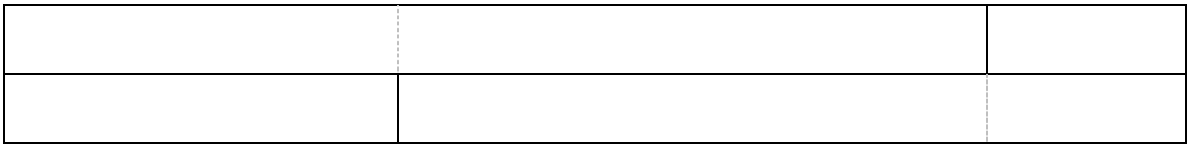
Returning to the earlier 'one-cell empty table' example, the table has one column with a width of 10,296 twentieths of a point. This measurement (twentieths of a point, or twips) is frequently used in WordprocessingML, and translates to 1/1440th of an inch (one-twentieth of a point, which is itself 1/72nd of an inch):.

```
<w:tblGrid>
  <w:gridCol w:w="10296"/>
</w:tblGrid>
```

Consider the following, more complex table that has two rows and two columns; the columns are not aligned:



This table is represented by laying out the cells on a table grid consisting of three table grid columns, each grid column representing a logical vertical column in the table:



The dashed lines represent the virtual vertical continuations of each table grid column, and the resulting table grid is represented as the following in WordprocessingML:

```
<w:tblGrid>
  <w:gridCol w:w="2952"/>
  <w:gridCol w:w="4416"/>
  <w:gridCol w:w="1488"/>
</w:tblGrid>
```

```
<w:tr>
  <w:tc>
    <w:tcPr>
      <w:tcW w:w="7368" w:type="dxa"/>
      <w:gridSpan w:val=”2”/>
    </w:tcPr>
    <w:p/>
  </w:tc>
  <w:tc>
    <w:tcPr>
      <w:tcW w:w="1488" w:type="dxa"/>
    </w:tcPr>
    <w:p/>
  </w:tc>
</w:tr>
<w:tr>
  <w:tc>
     <w:tcPr>
      <w:tcW w:w="2952" w:type="dxa"/>
    </w:tcPr>
    <w:p/>
  </w:tc>
  <w:tc>
    <w:tcPr>
      <w:tcW w:w="5904" w:type="dxa"/>
      <w:gridSpan w:val=”2”/>
    </w:tcPr>
    <w:p/>
  </w:tc>
</w:tr>
```

Notice that each of the cells which do not span one grid column (i.e., span two adjacent vertical lines) must specify this fact by supplying a gridSpan element with a value which determines how many grid columns this cell will span. Each gridCol element represents a shared 'column' in a table (to which the cells will snap) even if it doesn't appear visually.

2.5.4 Table Rows and Cells

A table row is defined using a tr element, which is analogous to the HTML <tr> tag. The tr element acts as a container for a row of cells with the table's content.

A tr element has one formatting child element, trPr, which defines the row properties (such as the row's width) and whether it can split across a page. Each property is defined by an individual child element under the trPr element. The complete set of table row properties can be found on the definition for the trPr element. As

well, a table row can contain two types of content: custom markup (custom XML or structured document tags), and table cells.

The cells in a row contain the table's content and are defined by tc elements, which are analogous to HTML <td> tags.

A tc element has one formatting child element, tcPr, which defines the properties for the cell. Each unique property is specified by a child element of this element. The complete set of table cell properties can be found on the definition for the tcPr element. As well, a table cell can contain any valid block-level content, which allows for the nesting of paragraphs and tables within table cells.

In the example below, the tcW element defines the width of the cell, where the attribute w is the value in twips. Here the width of the cell is 8,856 units, where *units* are defined by the attribute type. In this case, dxa represents twips.

```
<w:tr>
  <w:tc>
    <w:tcPr>
      <w:tcW w:w="8856" w:type="dxa"/>
    </w:tcPr>
    <w:p/>
  </w:tc>
</w:tr>
```

The tc element contains the cell's content, which, in this case, is an empty p element.

Consider a table having one cell, which contains the text "Hello, world":

Hello, world

This table's content is represented by the following XML:

```
<w:tr>
  <w:tc>
    <w:tcPr>
      <w:tcW w:w="1770" w:type="dxa"/>
    </w:tcPr>
    <w:p>
      <w:r>
        <w:t>Hello, World</w:t>
      </w:r>
    </w:p>
  </w:tc>
</w:tr>
```

At both the row and cell levels, the properties must also specify how the rows and cells will be placed on the table grid.

The trPr element contains information about the number of grid units which should be omitted ('skipped') before and after the row is complete using the gridBefore and gridAfter elements, allowing rows to start at different columns on the grid, as well as a preferred width for that leading/trailing space using the wBefore and wAfter elements. The tcPr element also contains grid information pertaining to how many grids a cell spans using the gridSpan element, which determines how many grid units are consumed by the current cell, as well as a preferred width for that cell using the tcW element.

In the earlier complex table having two rows of two differently sized cells, a consumer shall represent that table containing three grid columns (one per distinct vertical line). Consider the following XML for the first row of that table:

```
<w:tr>
  …
  <w:tc>
    <w:tcPr>
      <w:tcW w:w="5145" w:type="dxa" />
      <w:gridSpan w:val="2" />
    </w:tcPr>
    <w:p />
  </w:tc>
  <w:tc>
    <w:tcPr>
      <w:tcW w:w="2145" w:type="dxa" />
    </w:tcPr>
    <w:p/>
  </w:tc>
</w:tr>
```

Again, the gridSpan element is the number of grid columns that cell spans when being laid out on the table grid. In this example, the first cell of the first row contains two grid columns. As well, the cell specifies its preferred width using the tcW element, which tells the consumer the width desired by that cell at layout time.

It is important to note that every width in a table is a preferred width - because the table must satisfy the grid at all times, conflicting table properties must be resolved by overriding preferred widths in a specific manner, shown below.

2.5.5 Table Layout

Given the information shown in the table shown above, the table is specified as a series of properties:

- Table-level properties (e.g., preferred width)
- Table column grid

- Row-level properties (e.g., grid units before/after row start/end)
- Cell-level properties (e.g., number of grid units spanned)

In order to manipulate this set of properties into a table, the following logics are used, depending on the type of table:

2.5.6 Fixed Width Tables

The first type of table is a fixed width table, a table that does not dynamically resize based on its contents. In a fixed width table, the table information is used in the following manner:

- The table grid is used to create the set of shared columns in the table and their initial widths as defined in the tblGrid element
- The table's total width is defined based on the tblW property – if it is set to `auto` or `nil`, then the width is not yet determined and will be specified using the row and cell information.
- The first table row is read and the initial number of grid units before the row starts is skipped. The width of the skipped grid columns is set using the wBefore property.
- The first cell is placed on the grid, and the width of the specified grid column span set by gridSpan is set based on the tcW property.
- Each additional cell is placed on the grid.
- If at any stage, the preferred width requested for the cells exceeds the preferred width of the table, then each grid column is proportionally reduced in size to fit the table width.
- If the grid is exceeded (e.g., tblGrid specifies three grid columns, but the second cell has a gridSpan of three), the grid is dynamically increased with a default width for the new grid column.
- For each subsequent row, cells are placed on the grid, and each grid column is adjusted to be the maximum value of the requested widths (if the widths do not agree) by adding width to the last cell that ends with that grid column. Again, if at any point, the space requested for the cells exceeds the width of the table, then each grid column is proportionally reduced in size to fit the table width.

2.5.7 AutoFit Tables

In an AutoFit table (one which specifies that it should "AutoFit to table contents"), the table information is used in the following manner:

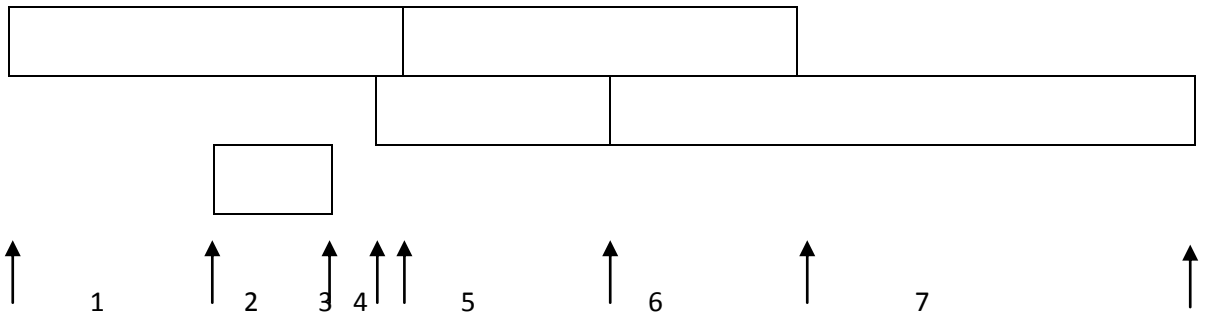
- Perform the steps above to lay out the fixed width version of the table.
- Calculate the minimum content width - the width of the cell's contents including all possible line breaking locations (or the cell's width, if the width of the content is smaller), and the maximum content width -the width of the cell's contents (assuming no line breaking not generated by explicit line breaks).
- The minimum and maximum content width of all cells that span a single grid column is the minimum and maximum content width of that column.
- For cells which span multiple grid columns, enlarge all cells which it spans as needed to meet that cell's minimum width.

- If any cell in a grid column has a preferred width, the first such width overrides the maximum width of the column's contents.
- Place the text in the cells in the table, respecting the minimum content width of each cell's content. If a cell's minimum content width exceeds the cell's current width, preferences are overridden as follows:
- First, override the column widths by making all other grid columns proportionally smaller until each it at its minimum width. This cell may then grow to any width between its own minimum and maximum width.
- Next, override the preferred table width until the table reaches the page width.
- Finally, force a line break in each cell's contents as needed

2.5.8 Complex Table Example

The properties above are best illustrated by example:

As shown above, table cells can be merged horizontally. This is represented with a single table cell whose gridSpan property defines the number of grid units consumed by that table cell for the current row. Consider the following fixed width table, which makes extensive use of resized and merged cells on what is actually just a seven-column grid. (The arrows point to each (invisible) vertical line of the grid and the numbers refer to the grid columns):



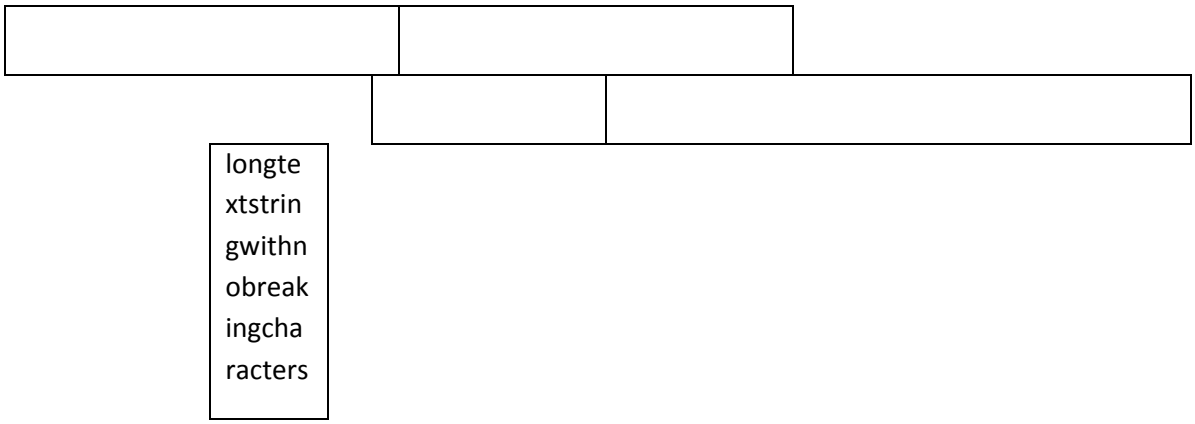
Although the table is visually complex, the standard rules apply: the first cell in the table is simply a cell which spans four grid units horizontally, as specified in the gridSpan element, and whose preferred with is 2952 twips, specified in the tcW element:

```
<w:tc>
  <w:tcPr>
    <w:tcW w:w="2952" w:type="dxa"/>
    <w:gridSpan w:val="4"/>
  </w:tcPr>
  <w:p/>
</w:tc>
```

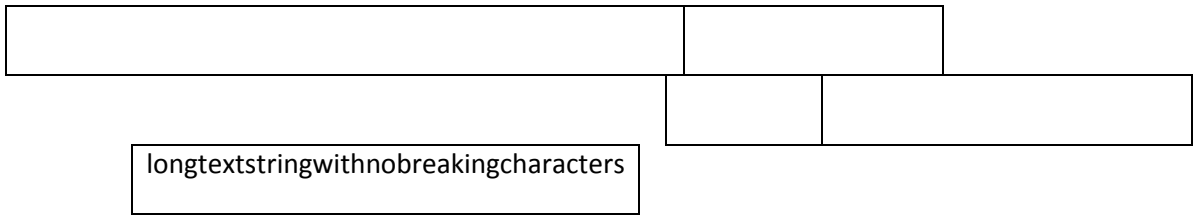
Similarly, all cells indented from the stand and end of the grid specify that indent using the gridBefore and gridAfter elements. For example, the XML for the second row in the table shows that that row starts three grid units into the table:

```
<w:tr>
  <w:trPr>
    <w:gridBefore w:val="3"/>
    <w:wBefore w:w="2748" w:type="dxa"/>
  </w:trPr>
  …
</w:tr>
```

If we take this fixed width table and introduce a long string into the single cell in row 3, we see that the presence of this text does not affect cell widths:



If we now turn on the AutoFit property and type into the cell in row three, which spans only grid column two, we see that the algorithm for this AutoFit table causes all cells in grid column two to increase in size, proportionally decreasing the other grid columns' size to accommodate the long non-breaking string in the last cell:



Each of the other grid columns was reduced, but since all columns are not at their minimum size, the table width is not increased even though the table is not yet at the page width.

2.5.9 Vertically Merged Cells

Although the previous examples may have implied that tables have strict definition of rows, table cells can also be merged vertically. The tcPr element may contain the vmerge element that defines the extent of vertically merged grid columns within a table. A vmerge element with its val attribute set to `restart` marks the start of a vertically merged cell range. A vmerge element with the val attribute set to `continue` (the default value)

marks the continuation of a vertically merged grid column. Cells between the first and last merged cell that are part of the vertical merge each must have a vmerge element to continue the vertical merge.

For example, consider a table with two rows and two columns:

First cell, first row	Last cell, first row
First cell, second row	Last cell, second row

Merging the two rows in the second column will result in the following table:

First cell, first row	Last cell, first row Last cell, second row
First cell, second row	

The last cell in the first row starts a merge that is completed in the cell below it, resulting in the following WordprocessingML:

```
<w:tr>
  <w:tc>
    <w:p>
      <w:r>
        <w:t>First cell, first row</w:t>
      </w:r>
    </w:p>
  </w:tc>
  <w:tc>
    <w:tcPr>
      <w:vmerge w:val="restart"/>
    </w:tcPr>
    <w:p>
      <w:r>
        <w:t>Last cell, first row</w:t>
      </w:r>
    </w:p>
    <w:p>
      <w:r>
        <w:t>Last cell, second row</w:t>
      </w:r>
    </w:p>
  </w:tc>
</w:tr>
```

```
<w:tr>
  <w:tc>
    <w:p>
      <w:r>
        <w:t>First cell, second row</w:t>
      </w:r>
    </w:p>
  </w:tc>
  <w:tc>
    <w:tcPr>
      <w:vmerge/>
    </w:tcPr>
    <w:p/>
  </w:tc>
</w:tr>
```

As shown, the vmerge with a value of `restart` begins (or restarts) a merged region, and the cell with no value is merged with the one above.

2.6 Custom Markup

Within a WordprocessingML document, it is often necessary for specific documents to contain semantic information beyond the presentation information specified by this Office Open XML specification. For example, an invoice document may wish to specify that a particular sentence of text is a customer name, in order for that information to be easily extracted from the document without the need to parse the text using regular expression matching or similar. For those cases, multiple facilities are provided for the insertion and round-tripping of customer defined semantics within a WordprocessingML document.

There are three distinct forms in which customer-defined semantics can be inserted into a WordprocessingML document, each with their own specific intended usage:

- Smart tags
- Custom XML markup
- Structured document tags (content controls)

The usage and presentation of each of these forms is described in the following sections.

2.6.1 Smart Tags

The first example of customer-defined semantics which can be embedded in a WordprocessingML document are smart tags. Smart tags allow semantic information to be added around an arbitrary run or set of runs within a document to provide information about the type of data contained within.

Consider the following text in a WordprocessingML document, with a smart tag around the stock symbol 'CNTS' (where the smart tag is displayed using a purple dotted underline):

This is a stock symbol: MSFT

This text would translate to the following WordprocessingML markup:

```
<w:p w:rsidR="00672474" w:rsidRDefault="00672474">
  <w:r>
    <w:t xml:space="preserve">This is a stock symbol: </w:t>
  </w:r>
  <w:smartTag w:uri="http://schemas.openxmlformats.org/2006/smarttags"
     w:element="stockticker">
    <w:r>
      <w:t>MSFT</w:t>
    </w:r>
  </w:smartTag>
</w:p>
```

As shown above, the smart tag is delimited by the smartTag element, which surrounds the run (or runs) which contain the text which is part of the smart tag.

The smart tag itself carries two required pieces of information, which together contain the customer semantics for this smart tag.

The first of these is the namespace for this smart tag (contained in the uri attribute). This allows the smart tag to specify a URI which should be round-tripped with this smart tag and be available to a consumer. It is intended to be used to specify a family of smart tags to which this one belongs – for example, in the sample above, the smart tag belongs to the `http://schemas.openxmlformats.org/2006/smarttags` namespace.

The second of these is the element name for this smart tag (contained in the element attribute). This allows the smart tag to specify a name which should be round-tripped with this smart tag and again available to a consumer. It is intended to be used to specify a unique name for this type of smart tag – for example, in the sample above, the smart tag specifies that its data is of type `stockticker`.

As well as the required information specified above, a smart tag can also contain any number of additional properties in namespace/name/value sets by adding them to the smart tag's property bag.

Using the example above, adding a new property called `fullCompanyName` with no namespace and value `Microsoft Corporation` to the smart tag would mean augmenting the output to add the smartTagPr element with this new property as follows:

```
    <w:smartTag w:uri="http://schemas.openxmlformats.org/2006/smarttags"
       w:element="stockticker">
    <w:smartTagPr>
      <w:attr w:name="fullCompanyName" w:val="Microsoft Corporation"/>
    </w:smartTagPr>
    <w:r>
      <w:t>MSFT</w:t>
    </w:r>
  </w:smartTag>
```

The resulting XML, as seen above, simply adds an attr element which specifies the property and value for the property bag.

A producer can embed a smart tag around any run-level content in a WordprocessingML document in order to embed additional information about the family and type of the data contained within. This allows 'tagging' of specific regions of a document with these semantics without need to provide context beyond the information provided in the uri and element attributes.

A consumer can read this smart tag data and provide additional functionality around these namespace/element pairs, which may or may not be specific to that smart tag type in the document. Examples of this functionality include: the ability to add/remove this markup via a user interface, ability to provide actions to operating in the context of this data type, etc.

2.6.2 Custom XML Markup

The next example of customer-defined semantics which can be embedded in a WordprocessingML document is custom XML markup. Custom XML markup allows the application of the XML elements defined in any valid XML Schema file to be applied to the contents of a WordprocessingML document in one of two locations: around a paragraph or set of paragraphs (at the block level); or around an arbitrary run or set of runs within a document (at the inline level) to provide semantics to that content within the context and structures defined by the associated XML Schema definition file.

The distinction between custom XML markup and smart tags is based on the fact that custom XML markup corresponds with the contents of a custom XML schema; which means that as shown below, custom XML markup can be used at the block-level to mark up the contents of a document on levels beyond that of one or more runs as well as on the inline (run) level. It can also be validated against a custom XML schema by a producer at run time.

Consider a simple XML Schema which defines two elements: a root element of invoice, and a child element of customerName - the first defining that this file's contents are an invoice, and the second specifying that the enclosed text as a customer's name:

invoice This is an invoice.

And this is a customer name: customerName Tristan Davis invoice

This output would translate to the following WordprocessingML markup:

```
<w:customXml w:uri="http://www.contoso.com/2006/invoice" w:element="invoice">
  <w:p>
    <w:r>
      <w:t>This is an invoice.</w:t>
    </w:r>
  </w:p>
  <w:p>
    <w:r>
      <w:t xml:space="preserve">And this is a customer name: </w:t>
    </w:r>
    <w:customXml w:uri="http://www.contoso.com/2006/invoice"
w:element="customerName">
      <w:r>
        <w:t>Tristan Davis</w:t>
      </w:r>
    </w:customXml>
  </w:p>
</w:customXml>
```

As shown above, each of the XML elements from the customer-supplied XML schema is represented within the document output as a customXml element.

Similar to the smart tag example above, a custom XML element in a document has two required attributes.

The first is the uri attribute, whose contents specify the namespace of the custom XML element in the document. In the example above, the elements each belong to the `http://www.contoso.com/2006/invoice namespace`.

The second is the element attribute, whose contents specify the name of the custom XML element at this location in the document. In the example above, the root element is called invoice and the child element is called customerName.

As well as the required information specified above, custom XML elements can also specify any number of attributes (as specified in the associated XML Schema) on the element. To add this information, the customXmlPr (properties on the custom XML element) specify one or more attr elements.

Using the example above, we can add a type attribute to the customerName element as follows:

```
<w:customXml w:uri="http://www.contoso.com/2006/invoice"
w:element="customerName">
  <w:customXmlPr>
    <w:attr w:uri="http://www.contoso.com/2006/invoice" w:name="type"
w:val="individual"/>
  </w:customXmlPr>
  <w:r>
    <w:t>Tristan Davis</w:t>
  </w:r>
</w:customXml>
```

The resulting XML, as seen above, simply adds an attr element which specifies the attribute for the custom XML element.

A producer can embed a custom XML element around or with block-level or run-level content in a WordprocessingML document in order to embed the structure of the customer-defined XML Schema within the WordprocessingML content. This allows 'tagging' of specific regions of a document with the semantics from this schema, while ensuring that the resulting file can be validated to the WordprocessingML schemas.

A consumer can read this custom XML markup and provide additional functionality around this customer-defined XML markup, which may or may not be specific to that type of XML in the document. Examples of this functionality include: the ability to add/remove this XML markup via a user interface, ability to provide actions to operating in the context of this data type, etc.

Each custom XML element is analogous to an XML element in the specified XML schema, and can be nested arbitrarily to any depth in the document. This facility is limited only by the XML Schema file itself, and the contents of the current document.

2.6.3 Structured Document Tags

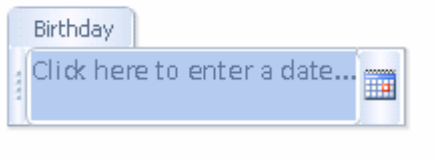
The final example of customer-defined semantics which can be embedded in a WordprocessingML document is the structured document tag (SDT).

As shown above, smart tags and custom XML markup each provide a facility for embedding customer-defined semantics into the document: smart tags, via the ability to provide a basic namespace/name for a run or set of runs within a documents; and custom XML markup, via the ability to tag the document with XML elements and attributes specified by any valid XML Schema file.

However, each of these techniques, while they each provide a way to add the desired semantic information, does not provide a way to affect the presentation or interaction within the document. To bridge these two worlds, structured document tags allow both the specification of customer semantics as well as the ability to influence the presentation of that data in the document.

This means that the customer can define the semantics and context of the tag, but can then use a rich set of pre-defined properties to define its behavior and appearance within the WordprocessingML document's presentation.

Consider a region which should be tagged with the semantic of "birthday", for the user to enter their date or birth into the document. Ideally, this region would also utilize a date picker to allow the user to enter the date from a calendar::



This content would translate to the following WordprocessingML markup:

```
<w:sdt>
  <w:sdtPr>
    <w:alias w:val="Birthday"/>
    <w:id w:val="8775518"/>
    <w:placeholder>
      <w:docPart w:val="DefaultPlaceholder_22479095"/>
    </w:placeholder>
    <w:showingPlcHdr/>
    <w:date>
      <w:dateFormat w:val="M/d/yyyy"/>
      <w:lid w:val="EN-US"/>
    </w:date>
  </w:sdtPr>
  <w:sdtContent>
    <w:p>
      <w:r>
        <w:rPr>
          <w:rStyle w:val="PlaceholderText"/>
        </w:rPr>
        <w:t>Click here to enter a date...</w:t>
      </w:r>
    </w:p>
  </w:sdtContent>
</w:sdt>
```

As shown above, each of the structured document tags in the WordprocessingML file is represented using the sdt element.

Within a structured document tag, there are two child elements which contain the definition and the content of this SDT. The first of these is the sdtPr element, which contains the set of properties specified for this structured document tag. The second is the sdtContent element, which contains all the content which is contained within this structured document tag.

2.6.3.1 Structured Document Tag Properties

Within the SDT's properties, various properties can be set which affect the appearance and behavior of this content in the document. These properties can be divided into four groups:

- Shared properties
- Locking properties
- Structured document tag type
- Type-specific properties

The complete set of properties for a structured document tag are found on the sdtPr element.

The first group is properties shared by all types of SDTs. These include, but are not limited to, the semantic name for the SDT, a unique ID (as an integer) that is round-tripped and allows the control to be uniquely identified across sessions, and a reference to a document building block that should be displayed as placeholder text.

The next group is the locking properties for the tag – these specify whether any consumer should allow the contents of the SDT to be edited, or the SDT itself to be deleted from the document.

The next group, the structured document tag's type, specifies how the content should be expressed in a document. These types include: plain text (all contents are of one formatting), rich text, date picker, combo box, drop-down list, and image. Each of the types provides user interface restrictions that restrict the contents to only those specified by the type (e.g., the picture cannot contain text).

Finally, the type-specific properties contain properties that are sensible in the context of that type. For example, the date format for a date picker or the drop-down list entries for a drop-down list/combo box. Type-specific properties are stored as children of the type's element.

Referring to the example above, the date properties are stored underneath the date element, as follows:

```
<w:sdtPr>
  ...
  <w:date>
    <w:dateFormat w:val="M/d/yyyy"/>
    <w:lid w:val="EN-US"/>
  </w:date>
</w:sdtPr>
```

This ensures that these properties are only available in the appropriate context(s).

2.6.3.2 Structured Document Tag Content

The second child of the sdt element is the sdtContent element, which contains all the content which is contained within this structured document tag.

2.6.3.3 XML Mapping

An additional property for SDTs allows their contents to be stored in another part (in particular, in the custom XML data storage within the file). The presence of the dataBinding element specifies that the contents of this SDT are simply a cache of the data stored at a particular XML element in a particular custom XML data storage part.

2.7 Sections

Within the main document story, there is also often a need for groupings of content on a basis larger than a paragraph (for example, ensuring that a specific set of paragraphs and tables are printed in landscape view, while ensuring that the remainder of the document is printed in portrait view). In order to group this content, a document can be divided into multiple *sections*, each of which defines a region of content in the document and allows the application of a set of section-level properties.

Consider a WordprocessingML document with two paragraphs of content, the first of which should be displayed on a page printed in portrait view, and the second of which should be displayed on a page printed in landscape view (the page content should be rotated 90 degrees to the left on the underlying page).

In order to have each of these paragraphs on different pages having different page orientation characteristics, this document would be split into two sections. Looking at the WordprocessingML for the example above:

```
<w:body>
  <w:p>
    <w:pPr>
      <w:sectPr>
        <w:pgSz w:w="12240" w:h="15840"/>
        <w:pgMar w:top="1440" w:right="1800" w:bottom="1440"
          w:left="1800" w:header="720" w:footer="720" w:gutter="0"/>
        <w:cols w:space="720"/>
        <w:docGrid w:linePitch="360"/>
      </w:sectPr>
    </w:pPr>
    <w:r>
      <w:t>This is sentence one.</w:t>
    </w:r>
  </w:p>
```

```
    <w:p>
      <w:r>
        <w:t>This is sentence two.</w:t>
      </w:r>
    </w:p>
    <w:sectPr>
      <w:pgSz w:w="15840" w:h="12240" w:orient="landscape"/>
      <w:pgMar w:top="1800" w:right="1440" w:bottom="1800"
        w:left="1440" w:header="720" w:footer="720" w:gutter="0"/>
      <w:cols w:space="720"/>
      <w:docGrid w:linePitch="360"/>
    </w:sectPr>
  </w:body>
```

This syntax defines two sections using two distinct sectPr elements: the first has a page size of 12,240 twentieths of a point wide and 15,640 twentieths of a point tall; the second has a page size of 15,640 twentieths of a point wide and 12,240 twentieths of a point tall, and is oriented in landscape mode.

2.7.1 Section Properties

As shown above, the end of a section is defined as a set of properties applied to the last paragraph in that section—converting that paragraph mark into a *section break* (i.e., a paragraph that closes a section).

Those properties are contained in a sectPr element, which is located within the paragraph properties (the pPr element) for the final paragraph in that section. Within the definition of section properties, the properties to be applied to that section (including, but not limited to, page size and orientation, line numbering settings, margins, and columns) are specified. The complete set of section properties is located on the definition for the sectPr element.

The only exception to this rule is the final set of section properties in this document. These are stored as the last child of the body element. This is done because the document's last paragraph must specify paragraph properties, and this syntax enforces that the final set of section properties are specified.

Going back to our example, the first section break is defined within the last paragraph for that section, but the last section properties are stored after the final paragraph.

```
<w:body>
  <w:p
    <w:pPr>
      <w:sectPr>
        <w:pgSz w:w="12240" w:h="15840"/>
        <w:pgMar w:top="1440" w:right="1800" w:bottom="1440"
          w:left="1800" w:header="720" w:footer="720" w:gutter="0"/>
        <w:cols w:space="720"/>
        <w:docGrid w:linePitch="360"/>
      </w:sectPr>
    </w:pPr>
    <w:r>
      <w:t>This is sentence one.</w:t>
    </w:r>
  </w:p>
  <w:p>
    <w:r>
      <w:t>This is sentence two.</w:t>
    </w:r>
  </w:p>
  <w:sectPr>
    <w:pgSz w:w="15840" w:h="12240" w:orient="landscape"/>
    <w:pgMar w:top="1800" w:right="1440" w:bottom="1800"
      w:left="1440" w:header="720" w:footer="720" w:gutter="0"/>
    <w:cols w:space="720"/>
    <w:docGrid w:linePitch="360"/>
  </w:sectPr>
</w:body>
```

2.7.2 Section Breaks

As well as specifying the section's properties, the type of section break is specified using the type element. WordprocessingML supports four distinct types of section breaks:

- *Next page section breaks* (the default if type is not specified), which begin the new section on the following page.
- *Odd page section breaks*, which begin the new section on the next odd-numbered page.
- *Even page section breaks*, which begin the new section on the next even-numbered page.
- *Continuous section breaks*, which begin the new section on the following paragraph. This means that continuous section breaks might not specify certain page-level section properties, since they must be inherited from the following section. These breaks, however, can specify other section properties, such as line numbering and footnote/endnote settings.

2.8 Styles

After looking at the primary elements of block-level content in a WordprocessingML file, it is now necessary to look at the information stored in the document that affects how this content is displayed.

The first such group of information is *styles*. Within a WordprocessingML file, *styles* are predefined sets of paragraph and/or character properties which can be applied to text within the document. This allows the formatting properties to be stored and managed independently from the content, allowing the look of document content to be changed in a single location (e.g., the look of all first-level headings is changed by changing the style with styleId `Heading1` rather than looking for and changing each paragraph in the document).

The Normal paragraph style in a word processing document can have any number of formatting properties, e.g., font face = Times New Roman; font size = 12pt; paragraph justification = left). All paragraphs that reference this paragraph style would automatically inherit these properties.

2.8.1 Styles Part

Style information in a WordprocessingML document is stored in the Styles part within the package, which is stored via an implicit relationship from the Main Document or Glossary Document part of relationship type `http://schemas.openxmlformats.org/wordprocessingml/2006/styles` and has a content type of `vnd-openxmlformats.officedocument.wordprocessingml-styles+xml`.

The styles part stores two types of style information for the document:

- Style definitions
- Latent style information

2.8.2 Style Definitions

Each style defined within a WordprocessingML document requires a *style definition*. The style definition contains all of the information needed by a consumer to store and display that style within a WordprocessingML document, and is defined using the style element. The style definition for any style in WordprocessingML can be divided into three segments (Note: the complete definition of style properties can be found on the reference for the style element):

- Common style properties
- Style ‘types’
- Type specific properties

Common style properties refer to the set of properties which can be used regardless of the type of style; for example, the style name, additional aliases for the style, a style ID (used by the document content to refer to the style), if style is hidden, if style is locked, etc.

Consider a style called Heading 1 in a document as follows:

```
<w:style w:type="paragraph" w:styleId="Heading1">
  <w:name w:val="heading 1"/>
  <w:basedOn w:val="Normal"/>
  <w:next w:val="Normal"/>
  <w:link w:val="Heading1Char"/>
  <w:priority w:val="1"/>
  <w:qformat/>
  <w:rsid w:val="00F303CE"/>
  …
</w:style>
```

Above the formatting information specific to this style type are a set of common style properties which define information shared by all style types.

Style types refer to the property on a style that defines the type of style created with this style definition. WordprocessingML supports six types of style definitions:

- Paragraph styles
- Character styles
- Linked styles (paragraph + character)
- Table styles
- Numbering styles
- Default paragraph + character properties

Consider a style called Heading 1 in a document as follows:

```
<w:style w:type="paragraph" w:styleId="Heading1">
  <w:name w:val="heading 1"/>
  <w:basedOn w:val="Normal"/>
  <w:next w:val="Normal"/>
  <w:link w:val="Heading1Char"/>
  <w:priority w:val="1"/>
  <w:qformat/>
  <w:rsid w:val="00F303CE"/>
  …
</w:style>
```

The type attribute has a value of `paragraph`, which indicates that the following style definition is a paragraph style.

2.8.3 Paragraph Styles

The first type of style definition, *paragraph styles* are styles that apply to the contents of an entire paragraph as well as the paragraph mark. This definition implies that the style can define both character properties (properties that apply to text within the document) as well as paragraph properties (properties which apply to

the positioning and appearance of the paragraph). Paragraph styles cannot be referenced by runs within a document, they must be referenced by the pStyle element within a paragraph's paragraph properties (pPr) element.

A paragraph style has three defining type-specific characteristics:

- The type attribute on the style has a value of paragraph, which indicates that the following style definition is a paragraph style.
- The next element defines an editing behavior which supplies the paragraph style to be automatically applied to the next paragraph when ENTER is pressed at the end of a paragraph of this style.
- The style specifies both paragraph-level and character-level properties using the pPr and rPr elements, respectively. In this case, the run properties are the set of properties applied to each run in the paragraph.

The paragraph style is then applied to paragraphs by referencing the styleId attribute value for this style in the paragraph properties' pStyle element.

Consider a paragraph style titled "Test Paragraph Style" which defines: paragraph spacing = double, paragraph indent = 1" (first line only); font = Algerian, font color = red, font size = 20 points. The resulting style definition would be:

```
<w:style w:type="paragraph" w:styleId="TestParagraphStyle">
  <w:name w:val="Test Paragraph Style"/>
  <w:qformat/>
  <w:rsid w:val="00F85845"/>
  <w:pPr>
    <w:spacing w:line="480" w:lineRule="auto"/>
    <w:ind w:firstLine="1440"/>
  </w:pPr>
  <w:rPr>
    <w:rFonts w:ascii="Algerian" w:hAnsi="Algerian"/>
    <w:color w:val="ED1C24"/>
    <w:sz w:val="40"/>
  </w:rPr>
</w:style>
```

Notice that the character properties for the style are under the rPr element, and the paragraph properties are under the pPr element.

The document content for a paragraph of this style would be:

```
<w:p>
  <w:pPr>
    <w:pStyle w:val="TestParagraphStyle"/>
  </w:pPr>
  <w:r>
    <w:t xml:space="preserve">Here is some fancy Text</w:t>
  </w:r>
</w:p>
```

The pStyle element links the paragraph with the style definition.

2.8.4 Character Styles

The next type of style definition, *character styles* are styles which apply to the contents of one or more runs of text within a document's contents. This definition implies that the style can only define character properties (properties which apply to text within a paragraph) because it cannot be applied to paragraphs. Character styles can only be referenced by runs within a document, and they must be referenced by the rStyle element within a run's run properties element.

A character style has two defining type-specific characteristics:

- The type attribute on the style has a value of `character`, which indicates that the following style definition is a character style.
- The style specifies only character-level properties using the rPr element. In this case, the run properties are the set of properties applied to each run which is of this style.

The character style is then applied to runs by referencing the styleId attribute value for this style in the run properties' rStyle element.

Consider a character style titled "Test Character Style" which defines; font = Courier New, font color = yellow; underline. The resulting style definition would be:

```
<w:style w:type="character" w:styleId="TestCharacterStyle">
  <w:name w:val="Test Character Style"/>
  <w:priority w:val="99"/>
  <w:qformat/>
  <w:rsid w:val="00E77BF0"/>
  <w:rPr>
    <w:rFonts w:ascii="Courier New" w:hAnsi="Courier New"/>
    <w:color w:val="FFF200"/>
    <w:u w:val="single"/>
  </w:rPr>
</w:style>
```

Notice that the character properties applied using this style are under the rPr element. The document content for a paragraph with a run of this style would be:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">The following text is in the </w:t>
  </w:r>
  <w:r>
    <w:rPr>
      <w:rStyle w:val="TestCharacterStyle"/>
    </w:rPr>
    <w:t>character style</w:t>
  </w:r>
  <w:r>
    <w:t>.</w:t>
  </w:r>
</w:p>
```

The rStyle element in the second run links that run with the style definition, inheriting the formatting properties for that run.

2.8.5 Linked Styles

The next type of style definition, *linked styles* are actually a paired combination of styles which can be applied to the contents of one or more runs of text within a document's contents or the entire contents of one or more paragraphs in a WordprocessingML document. This definition implies that the style can define both a set of character properties (properties which apply to text within a paragraph) as well as a set of paragraph properties (properties which apply to the positioning and appearance of the paragraph) because it must be possible to apply the style to paragraphs as well as characters.

In order to accomplish these dual uses, a linked style is actually a pairing of a paragraph style and a character style in the WordprocessingML document. Each style exists uniquely within the styles part, but are linked by the link element, which specifies that these styles are each half of a linked style definition and should be treated as one style at runtime.

A typical example of the use of a linked style is a quote style - if the style is applied to a paragraph, the quoted text should be indented additionally to create a block quote effect, but if the style is applied to text in a paragraph, only the character level effects should be applied.

Consider the following two styles which comprise a linked style pairing:

```
<w:style w:type="paragraph" w:styleId="TestLinkedStyle">
  <w:name w:val="Test Linked Style"/>
  <w:link w:val="TestLinkedStyleChar"/>
  <w:qformat/>
  <w:rsid w:val="009C1646"/>
```

```
      <w:pPr>
        <w:spacing w:line="480" w:lineRule="auto"/>
        <w:ind w:left="1440"/>
      </w:pPr>
      <w:rPr>
        <w:rFonts w:ascii="Arial" w:hAnsi="Arial"/>
        <w:color w:val="22B14C"/>
      </w:rPr>
    </w:style>
    <w:style w:type="character" w:styleId="TestLinkedStyleChar">
      <w:name w:val="Test Linked Style Char"/>
      <w:link w:val="TestLinkedStyle"/>
      <w:rsid w:val="009C1646"/>
      <w:rPr>
        <w:rFonts w:ascii="Arial" w:hAnsi="Arial"/>
        <w:color w:val="22B14C"/>
      </w:rPr>
    </w:style>
```

The link element in the paragraph style specifies `TestLinkedStyleChar`, the styleId of the paired character style, and the link element in the character style specifies `TestLinkedStyle`, the styleId of the paired paragraph style, creating a linked style combination.

Paragraph-level instances of linked styles can only be referenced by paragraphs within a document, and they must be referenced by the pStyle element within the paragraph's paragraph properties element (pPr), which must referrence the paragraph version of the linked style. Character-level instances of linked styles can only be referenced by a run's run properties element (rPr) within a document, and they must be referenced by the rStyle element within the run properties element which must reference the character version of the linked style.

Consider a linked style titled "Test Linked Style" which defines; font = Arial, font color = green; paragraph spacing = double, indent = 1" left. The resulting style definitions would be:

```
    <w:style w:type="paragraph" w:styleId="TestLinkedStyle">
      <w:name w:val="Test Linked Style"/>
      <w:link w:val="TestLinkedStyleChar"/>
      <w:qformat/>
      <w:rsid w:val="009C1646"/>
      <w:pPr>
        <w:pStyle w:val="TestLinkedStyle"/>
        <w:spacing w:line="480" w:lineRule="auto"/>
        <w:ind w:left="1440"/>
      </w:pPr>
```

```
    <w:rPr>
      <w:rFonts w:ascii="Arial" w:hAnsi="Arial"/>
      <w:color w:val="22B14C"/>
    </w:rPr>
  </w:style>
  <w:style w:type="character" w:styleId="TestLinkedStyleChar">
    <w:name w:val="Test Linked Style Char"/>
    <w:link w:val="TestLinkedStyle"/>
    <w:rsid w:val="009C1646"/>
    <w:rPr>
      <w:rFonts w:ascii="Arial" w:hAnsi="Arial"/>
      <w:color w:val="22B14C"/>
    </w:rPr>
  </w:style>
```

Notice that the linked style definition is composed of the paragraph style, which specifies both the run and paragraph properties, and the character style, which specifies only the run properties. The document content for a paragraph with this linked style would be:

```
  <w:p>
    <w:pPr>
      <w:pStyle w:val="TestLinkedStyle"/>
    </w:pPr>
    <w:r>
      <w:t xml:space="preserve">A para version of Test Linked Style.</w:t>
    </w:r>
  </w:p>
```

The pStyle element in the paragraph's properties links the paragraph with the paragraph version of the linked style definition.

The document content for a paragraph with a run of this linked style would be:

```
  <w:p>
    <w:r>
        <w:t xml:space="preserve">Next run is character version of </w:t>
    </w:r>
    <w:r>
      <w:rPr>
        <w:rStyle w:val="TestLinkedStyleChar"/>
      </w:rPr>
      <w:t>Test Linked Style</w:t>
    </w:r>
```

```
    <w:r>
      <w:t>.</w:t>
    </w:r>
  </w:p>
```

The rStyle element in the second run's properties links the run with the character version of the linked style definition.

2.8.6 Numbering Styles

Numbering styles are style definitions which specify common style properties for a multi-level numbering format within a document. This means that a numbering style defines only a single paragraph property: a reference to a numbering definition stored in the document's numbering part, using the numPr element.

Unlike paragraph and character styles, numbering styles are never directly referenced by content in the document – instead, an abstract numbering definition (covered in the numbering topic of this section) specifies that it is actually the underlying numbering information for a numbering style.

Consider a numbering style "Test Numbering Style":

```
<w:style w:type="numbering" w:styleId="TestNumberingStyle">
  <w:name w:val="Test Numbering Style" />
  <w:priority w:val="99" />
  <w:rsid w:val="0045009F" />
  <w:pPr>
    <w:numPr>
      <w:numId w:val="1" />
    </w:numPr>
  </w:pPr>
</w:style>
```

The only information specified in the numbering style definition is a reference to the numbering definition for the numbering information which is defined by this numbering style.

2.8.7 Table Styles

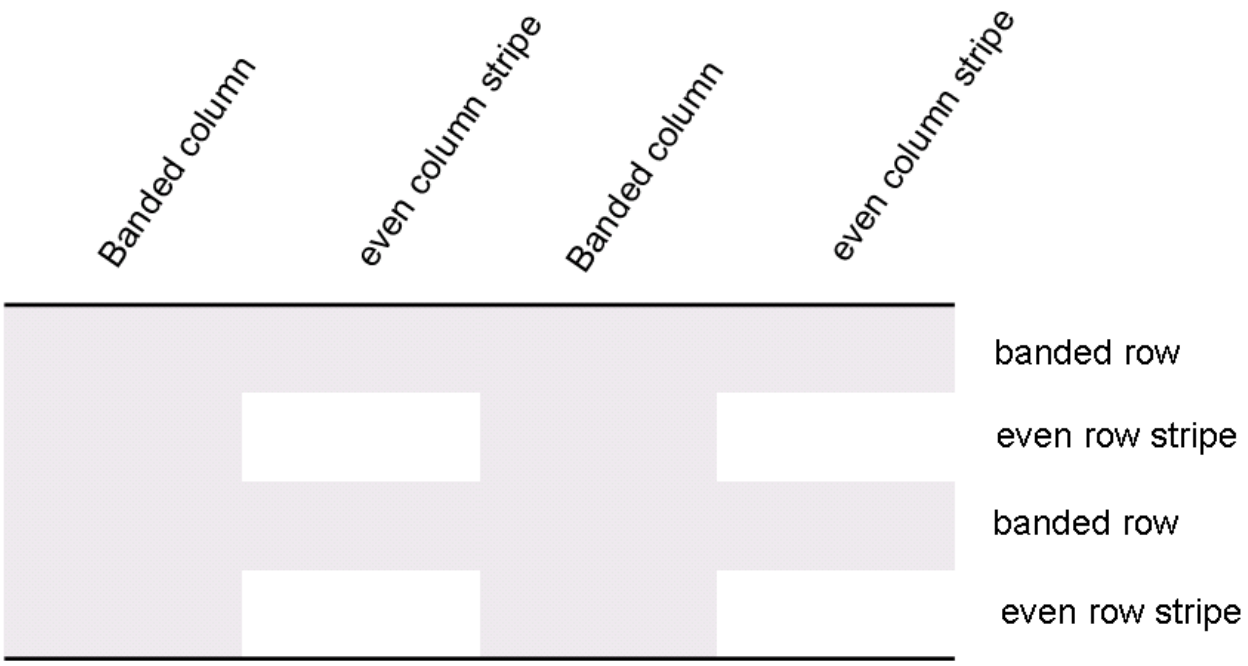
The last conventional type of style definition, table styles are styles which apply to the contents of zero or more tables within a document. This definition implies that the style can only define table properties (properties which apply to the table and its constituent rows and cells), however a table style can also define paragraph properties (properties which apply to the positioning and appearance of paragraphs) as well as character properties (properties which apply to runs) for all of the paragraphs and runs within the specified table in the document. Table styles can only be referenced by tables within a document, and they must be referenced by the tblStyle element within a table's table properties (tblPr) element.

Like the style definitions discussed above, table styles specify all of the properties that can be applied to a table, as well as paragraph and character properties for the table's contents. However, unlike other style definitions, table styles allow for the definition of conditional formats for different regions of the table.

These table conditional formats are applied to different regions of the table as follows:

Top left cell	Header row	Top right cell
First column	Table body	Last column
Bottom left cell	Footer row	Bottom right cell

All rows in the table can also have conditional formatting on an alternating row/column basis as well as follows:



When specified, these conditional formats are applied in the following order (therefore subsequent formats override properties on previous formats):

- Whole table
- Banded columns, even column banding
- Banded rows, even row banding
- First row, last row
- First column, last column
- Top left, top right, bottom left, bottom right

Consider a table style “Test Table Style” defined as follows: all cells with 1pt table borders on all sides, 0.1” cell margins on left and right of cells, and 0” cell margins on top and bottom of cells, as well as header row specific formatting of: red shading, bold text as follows:

```
<w:style w:type="table" w:styleId="TestTableStyle">
  <w:name w:val="Test Table Style"/>
  <w:basedOn w:val="TableNormal"/>
  <w:priority w:val="99"/>
  <w:rsid w:val="00340CC4"/>
  <w:tblPr>
    <w:tblBorders>
      <w:top w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:left w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:bottom w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:right w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:insideH w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:insideV w:val="single" w:sz="4" w:space="0" w:color="auto"/>
    </w:tblBorders>
    <w:tblCellMar>
      <w:top w:w="0" w:type="dxa"/>
      <w:left w:w="108" w:type="dxa"/>
      <w:bottom w:w="0" w:type="dxa"/>
      <w:right w:w="108" w:type="dxa"/>
    </w:tblCellMar>
  </w:tblPr>
  <w:tblStylePr w:type="firstRow">
    <w:rPr>
      <w:b/>
    </w:rPr>
    <w:tcPr>
      <w:shd w:val="clear" w:color="auto" w:fill="ED1C24"/>
    </w:tcPr>
  </w:tblStylePr>
</w:style>
```

The tblPr element holds the formatting which is applied to the entire table, and the tblStylePr element with a type attribute value of `firstRow` holds the formatting for the first table row, specifically the bold run property and red cell shading.

An individual instance of a table defines an association with a table style using the tblStyle element in the table's properties (tblPr), as discussed above. However, individual tables can choose whether to apply the following aspects of the table's conditional formats individually:

- First row
- Last row
- First column
- Last column
- Row banding
- Column banding

The use or omission conditional formats are specified using the tblLook element, which contains a bitmask representing which properties are applied and omitted.

Consider two tables using the table style "Style2"; one which specifies that it should only use the header row and footer row conditional formatting properties from the table style, and the other which specifies that it should use the header row, footer row, and banded row conditional formatting:

```
<w:tbl>
  <w:tblPr>
    <w:tblStyle w:val="Style2"/>
    <w:tblW w:w="0" w:type="auto"/>
    <w:tblLook w:val="0660"/>
  </w:tblPr>
  …
</w:tbl>
…
<w:tbl>
  <w:tblPr>
    <w:tblStyle w:val="Style2"/>
    <w:tblW w:w="0" w:type="auto"/>
    <w:tblLook w:val="0460"/>
  </w:tblPr>
  …
</w:tbl>
```

The tables each specify the appropriate set of conditional formats using the tblLook element, as seen by the identical table styles in the tblStyle element, and different tblLook values.

2.8.8 Default Document Paragraph and Character Properties

The final type of style in a WordprocessingML document is the default paragraph and character properties for the document. Although this is not a style in the strict sense of the word (because this property set cannot directly be applied to text) it defines the basic set of formatting properties which are inherited by paragraphs and runs in the document.

The following section, entitled Style Inheritance, explains exactly how the default document paragraph and character properties influence the appearance of all content in the document.

2.8.9 Style Inheritance

In order to compile the complete set of paragraph and character properties specified by any given style (as appropriate), a consumer must follow the rule of style inheritance to determine each property in that set.

Style inheritance states that styles of any given type may inherit from other styles of that type, and therefore a consumer must 'build up' the style information by following the inheritance tree. This inheritance is defined via the basedOn element, which specifies the styleId of the parent style.

The "Tristan Test" paragraph style can inherit properties from the "Heading 1" paragraph style, which itself can inherit properties from the "Normal" paragraph style.

To build up the resulting style, a consumer must trace the hierarchy (following each basedOn value) back to a style which has no basedOn element (is not based on another style). The resulting style is then constructed by following each level in the tree, applying the specified paragraph and/or character properties as appropriate. When properties conflict, they are overridden by each subsequent level (this includes turning OFF a property set at an earlier level). Properties which are not specified simply do not change those specified at earlier levels.

Consider a character style "Green" which specifies only that the text color is green, but inherits from another character style "Base" which defines a font face of Arial, as well as bold:

```
<w:style w:type="character" w:styleId="Green">
  <w:name w:val="Green" />
  <w:basedOn w:val="Base" />
  <w:rPr>
    <w:color w:val="22B14C" />
  </w:rPr>
</w:style>
  …
../Local Settings/Temp/styles.xml<w:style w:type="character" w:styleId="Base">
  <w:name w:val="Base" />
  <w:rPr>
    <w:rFonts w:ascii="Arial" w:hAnsi="Arial" />
    <w:b />
  </w:rPr>
</w:style>
```

The definition of the Green character style has a basedOn element which specifies the Base style. This means that any use of the Green style is defined as bold, green, Arial text.

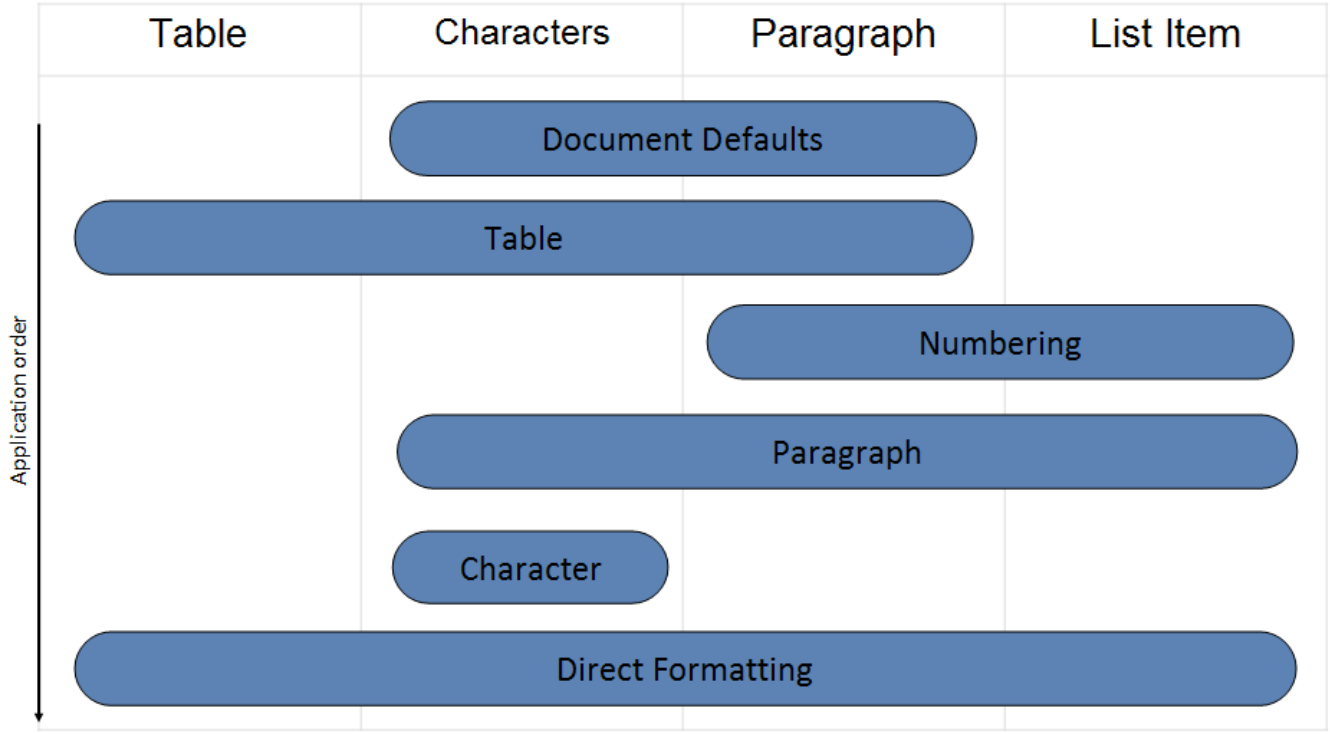
Conversely, a producer should not output any property on a style which has already been set by a previous level of the style hierarchy, as well as those which match the document defaults. This means that if the document defaults or any previous level in a style's hierarchy specify a property which is unchanged at this level, that property should not be part of the style definition in the resulting WordprocessingML. Adding a property at multiple levels in the style hierarchy is not invalid, but unnecessarily duplicative as the setting is already applied to the text, resulting in an unnecessary increase to file size.

If the document default font is Bauhaus 93 and the Heading 1 style also specifies the Bauhaus 93 font, then a producer should not output any rFonts element for the Heading 1 style definition, because that formatting is inherited from the document defaults.

2.8.10 Style Application

With the various flavors of styles available, multiple style types can be applied to the same content within a file, which means that properties must be applied in a specific deterministic order. As with inheritance, the resulting formatting properties set by one type can be unchanged, removed, or altered by following types.

The following table illustrates the order of application of these defaults, and which properties are impacted by each:



This process can be described as follows: First, the document defaults are applied to all runs and paragraphs in the document. Next, the table style properties are applied to each table in the document, following the conditional formatting inclusions and exclusions specified per table. Next, numbered item and paragraph properties are applied to each paragraph formatted with a numbering style. Next, paragraph and run properties are applied to each paragraph as defined by the paragraph style. Next, run properties are applied to each run with a specific character style applied. Finally, we apply direct formatting (paragraph or run properties not from styles).

2.8.11 Latent Styles

The final piece of information stored in the styles part in the document, aside from style definition information, is *latent style* information.

Latent styles are all styles contained in a document's template which have not yet been instantiated (used) in the current instance of the document.

In WordprocessingML, there are often properties which must be set on all styles in a document template regardless of whether they are being used: for example, whether or not the style can be applied in the current document (locked state), UI sorting priority, whether the style should be shown in the user interface, etc. In order for the document to function correctly, it is essential that this information is stored within the document, so that a consumer can determine the necessary style information from the document alone (without access to the template). However, it would be grossly inefficient for the document to store all style information for all styles simply to store this information, so latent styles are used to store just the necessary style properties without caching all style information in the document.

In order to do this efficiently, the document declares a latentStyles element in the styles part which defines the default properties applied to all latent styles in the document. All styles whose properties do not match the default for the set of style properties which must be defined for all styles are explicitly defined using the lsdException element.

Consider the following latent style information stored in a document's styles part:

```
<w:latentStyles w:defLockedState="off" w:defPriority="99"
  w:defSemiHidden="on" w:defUnhideWhenUsed="on" w:defQFormat="off"
  w:count="180">
  <w:lsdException w:name="Normal" w:unhideWhenUsed="off"
    w:qformat="on"/>
  <w:lsdException w:name="heading 1" w:semiHidden="off" w:priority="1"/>
  <w:lsdException w:name="heading 2" w:priority="1"
    w:unhideWhenUsed="on"/>
  <w:lsdException w:name="heading 3" w:semiHidden="off/>
  <w:lsdException w:name="heading 4" w:priority="1" w:qformat="on"/>
  <w:lsdException w:name="heading 5" w:priority="1" w:qformat="on"/>
```

```
    <w:lsdException w:name="heading 6" w:priority="1" w:qformat="on"/>
    <w:lsdException w:name="heading 7" w:priority="1" w:qformat="on"/>
    <w:lsdException w:name="heading 8" w:priority="1" w:qformat="on"/>
    <w:lsdException w:name="heading 9" w:priority="1" w:qformat="on"/>
    <w:lsdException w:name="Normal Indent" w:priority="6" w:qformat="on"/>
  </w:latentStyles>
```

The attributes on the latentStyles element define the properties applied to all latent styles for this document. All styles whose properties do not match the default latent styles properties are explicitly defined using the values on the lsdException elements.

2.9 Fonts

2.9.1 Font References

Within a WordprocessingML document, font face information can be referenced by any set of run properties, both as part of a style definition or direct formatting on one or more runs in the document's contents. This reference is established by referencing the primary name of the font face that is used in the rFonts element of the run properties, linking that run with the desired font face.

For example, consider a run of text that has been directly formatted to use the `Arial Black` font face. This setting would be specified as follows on the run's properties:

```
  <w:r>
    <w:rPr>
      <w:rFonts w:ascii="Arial Black" w:hAnsi="Arial Black" />
    </w:rPr>
    <w:t>This run of text uses the Arial Black font face.</w:t>
  </w:r>
```

The rFonts element specifies that the run should be formatted using the `Arial Black` font face. Applications can then look up and use the font with primary name of `Arial Black` when formatting this run.

2.9.2 Font Reference Types

In the example above, two attributes were present, both referring to the font face with primary name `Arial Black`. This simple case illustrates the ability for a WordprocessingML document to store up to four fonts which may be used on the contents of a run, as follows:

- ASCII font
- High ANSI font
- East Asian font
- Complex Script font

Each of these font faces is used to format the characters in the run that fall under their purview:

The *ASCII font* formats all characters in the ASCII range (character values 0–127). This font is specified using the ascii attribute on the rFonts element.

The *East Asian font* formats all characters that belong to Unicode sub ranges for East Asian languages. This font is specified using the eastAsia attribute on the rFonts element.

The *complex script font* formats all characters that belong to Unicode sub ranges for complex script languages. This font is specified using the cs attribute on the rFonts element.

The *high ANSI font* formats all characters that belong to Unicode sub ranges other than those explicitly included by one of the groups above. This font is specified using the hAnsi attribute on the rFonts element.

For example, consider a run of text defined as follows:

```
<w:r>
  <w:rPr>
    <w:rFonts w:ascii="Arial Black" w:hAnsi="Arial Black" w:cs="Arial"
      w:eastAsia="SimSun"/>
  </w:rPr>
  …
</w:r>
```

The rFonts element specifies that the contents of this run are formatted as follows:

- Complex script characters used the `Arial` font
- East Asian characters used the `SimSun` font
- All other characters used the `Arial Black` font

2.9.3 Ambiguous Characters

When classifying characters into one of the four slots defined above, it is likely that the classification of some characters will be ambiguous (the resulting classification would be equally applicable for one or more font slots).

To handle this, the font face information can also include a hint, which specifies how ambiguous mappings are resolved into a font slot. This information is stored on the hint attribute on the rFonts element, and specifies the bucket into which these ambiguous characters fall.

For example, if the hint attribute has a value of `eastAsia`, then all ambiguous characters shall be formatted using the East Asian font face.

2.9.4 Font Table

Within a document, the *font table* contains information about the fonts used in the document to allow:

- Applications to perform substitution with the most appropriate possible font when the desired font face is not available on the system. Since some fonts are commercially distributed, it is possible for a

document to be formatted with one or more fonts that are not available depending on the machine opening the current system. This information allows the application that cannot locate the desired font to perform the most appropriate possible match.

- Embedding of fonts in the document to prevent the need for font substitution

The font table part is stored via an implicit relationship from either the main document part or the glossary document part, and has a relationship type of http://schemas.openxmlformats.org/wordprocessingml/2006/fontTable, and a content type of vnd-openxmlformats.officedocument.wordprocessingml-fontTable+xml.

2.9.5 Font Substitution Data

The first classification of data stored in the font table are an optional set of font metrics which are queried from the font and stored in the document such that future applications can utilize them when the desired font is not available. If a particular font face cannot be located on the current system, then this data is used to substitute a font that most appropriately matches its characteristics.

For example, consider the font substitution data stored for the `Arial Black` font:

```
<w:font w:name="Arial Black">
  <w:panose1 w:val="020B0A04020102020204" />
  <w:charset w:val="00" />
  <w:family w:val="swiss" />
  <w:pitch w:val="variable" />
  <w:sig w:usb0="00000287" w:usb1="00000000" w:usb2="00000000"
    w:usb3="00000000" w:csb0="0000009F" w:csb1="00000000" />
</w:font>
```

This data is linked to the font face with a name of `Arial Black` via the name attribute, and stores the following information about the font (see the reference material on fonts for more details):

- The font's Panose-1 number
- The character set of the font
- The font's family
- The font's pitch
- The code pages and Unicode sub ranges supported by the font

2.9.6 Font Embedding

As well as providing information about the font's metrics, applications may be directed to embed the contents of a font (partially or as a whole) into a document, a process known as font embedding. *Font embedding* literally embeds an obfuscated version of the font into the file so that it may be retrieved and used to view the contents of this document - but the obfuscation ensures that the font cannot be extracted and used for any other document (as it may have a commercial license).

Within the font table, when a font is embedded there are explicit relationships to each font form needed:

- Regular
- Bold
- Italic
- Bold + Italic

Each form is obfuscated using the mechanism described in the reference material on this subject.

2.9.7 Theme Fonts

As well as storing standard font face information, run properties may store an abstraction for font face information known as theme fonts. *Theme fonts* are values that specify that the font face information for a run is not stored in the attribute value using the appropriate font face name, but is rather a reference into the document's theme part, allowing font face information to be stored and managed centrally as part of the theme data. It is appropriate to think of theme fonts as a "style for fonts" in the same way in which a style is a reference to the formatting that is stored centrally in another part.

Theme fonts are specified using the theme attribute variants in the rFonts element, rather than storing the actual font face name.

For example, consider a run of text defined as follows:

```
<w:r>
  <w:rPr>
    <w:rFonts w:asciiTheme="minorHAnsi" w:hAnsiTheme="minorHAnsi" />
  </w:rPr>
  …
</w:r>
```

The rFonts element's attribute values of asciiTheme and hAnsiTheme both store a reference to a theme font stored in the document's theme part (i.e., there is no font with the primary name `minorHAnsi`).

Once this information has been established, it is combined with the theme language data stored in the document's settings to resolve the appropriate theme fonts from the theme part. The syntax and format of the theme part are stored in the DrawingML syntax and discussed in that section.

2.10 Numbering

Numbering in WordprocessingML refers to symbols—Arabic numerals, Roman numerals, symbol characters ("bullets"), text strings, etc.—that are used to label individual paragraphs of text.

The following two paragraphs each contain numbering as defined by WordprocessingML: the first uses an Arabic numeral, the second a symbol character:

1. This is a paragraph with numbering information.

- This is also a paragraph with numbering information.

2.10.1 Numbering Part

Numbering information in a WordprocessingML document is stored in the Numbering part within the package, which is stored via an implicit relationship from the Main Document part or Glossary Document part of relationship type `http://schemas.openxmlformats.org/wordprocessingml/2006/numbering` and has a content type of `vnd-openxmlformats.officedocument.wordprocessingml-numbering+xml`.

2.10.2 Numbering Definitions

The specification of a specific set of numbering information is called a *numbering definition*. Numbering definitions are stored in two components:

- Abstract numbering definitions
- Numbering definition instances

As shown below, their relationship is (essentially) that of an abstract and an inherited class.

2.10.3 Abstract Numbering Definitions

An *abstract numbering definition* is the basis for all numbering information in a WordprocessingML document, as it defines the appearance and behavior of a specific set of numbered paragraphs in a document, and is defined using the abstractNum element. Although abstract numbering definitions contain all of the numbering information for one type of numbering, they cannot be directly referenced by content (hence their abstract designation), they must be inherited by a numbering definition instance, which itself can be referenced by content. A specific abstract numbering definition in WordprocessingML can be divided into two parts:

- Common numbering properties
- Numbering levels

The complete definition of all abstract numbering properties can be found in the reference for the abstractNum element.

Common numbering properties refer to the properties that can be specified by all abstract numbering definitions regardless of their contents. Examples of common numbering properties include: a numbering ID (which uniquely identifies a numbering definition), the numbering definition type (single level, multi-level, multi-level hybrid), the numbering name, and optional numbering style references, as discussed in detail later in this subclause.

Consider the following example of an abstract numbering definition in a WordprocessingML document:

```
<w:abstractNum w:abstractNumId="4">
  <w:nsid w:val="1DE04504" />
  <w:multiLevelType w:val="hybridMultilevel" />
  <w:lvl w:ilvl="0" w:tplc="0409000F">
    …
  </w:lvl>
```

```
    <w:lvl w:ilvl="1" w:tplc="04090019">
      …
    </w:lvl>
    <w:lvl w:ilvl="2" w:tplc="04090019">
      …
    </w:lvl>
    <w:lvl w:ilvl="3" w:tplc="0409000F">
      …
    </w:lvl>
    …
  </w:abstractNum>
```

This numbering definition specifies two common properties: a numbering ID (using the nsid element) of 1DE04504, and a list type (using the multiLevelType element) of hybridMultilevel, which specifies that this abstract numbering definition is more than one level and contains multiple numbering formats.

The other part of an abstract numbering definition is the specification of one or more numbering levels, each of which defines a unique set of formatting properties for one level in this numbering definition.

Consider three numbered paragraphs that reference the same numbering definition, but each, in turn, reference a different level within that list:

1. One
    a. Two
        i. Three

Although the paragraphs each reference the same abstract numbering definition (which is discussed later), each refers to a separate level within that abstract numbering definition, and therefore each has a unique set of paragraph and numbering properties.

It is important to note that the concept of levels in an abstract numbering definition refers to the levels as defined in the file format, and in no way the logical indentation of numbered paragraphs within a WordprocessingML document.

Consider another set of numbered paragraphs in WordprocessingML, where each subsequent paragraph is a different level but references the same abstract numbering definition:

1) Level one
    a) Level two
i) Level three
    (1) Level four
        (a) Level five

In this example, the properties of each level of the numbering definition is such that the paragraphs for each level are indented arbitrarily. However, this is still a completely valid numbering definition, and the paragraphs each represent subsequent levels of the same numbering definition.

Within an abstract numbering level definition, each numbering level is represented by an lvl element that defines a single level of numbering information. Numbering levels specify the following properties: starting number value, a number format presentation code (e.g., 1 vs. the string literal One), an associated paragraph style, which previous level should cause this numbering level to restart, the numbering text, number justification, a paragraph properties indentation for this level, etc. The complete definition of all numbering level properties can be found on the reference for the lvl element.

Consider the following numbering level definition in WordprocessingML:

```
<w:lvl w:ilvl="1">
  <w:start w:val="4"/>
  <w:nfc w:val="3"/>
  <w:pStyle w:val="Heading1"/>
  <w:lvlText w:val="BEFORE %2 AFTER %1 END"/>
  <w:lvlJc w:val="left"/>
  <w:pPr>
    <w:tabs>
      <w:tab w:val="num" w:pos="2880"/>
    </w:tabs>
    <w:ind w:left="288" w:firstLine="1152"/>
  </w:pPr>
</w:lvl>
```

This particular numbering level defines the following information:

- This is level 1 (the second level) for this numbering definition
- Start at number 4
- Use number format 3 (which translates to 1, 2, 3, and so on)
- When this level is used, apply the Heading1 style
- Use the following level text for the number: BEFORE %2 AFTER %1 END
- Left justify the number
- Set a left indent of 288 twentieths of a point, and a first line indent of 1152 twentieths of a point

This information is used to display the number for paragraphs of level 1 the reference this numbering definition.

Of particular significance is the lvlText element, which defines the content of the number text for each numbering level. Its syntax allows any string literal to be placed in the number (e.g., the ARTICLE in ARTICLE I, ARTICLE II, ARTICLE III, and so on), as well as the current value of the number for this or any previous level in the list.

Referring to the numbering level definition above, the lvlText is defined as follows:

```
<w:lvlText w:val="BEFORE %2 AFTER %1 END"/>
```

This level text specifies three literal strings (BEFORE, AFTER, END) mixed with the current numbering value from level 1 and level 0 in the document. Therefore, assuming level 0 is just a simple number, when inserted it would read:

```
1
  BEFORE 1 AFTER 1 END
  BEFORE 2 AFTER 1 END
  BEFORE 3 AFTER 1 END
2
  BEFORE 1 AFTER 2 END
  BEFORE 2 AFTER 2 END
  …
```

The %1 and %2 values correspond to the value for level 0 and 1 of this list, respectively.

2.10.4 Numbering Definition Instances

A numbering definition instance is a specific instantiation of numbering information that can be referenced by zero or more paragraphs within the document. A numbering definition instance is defined using the num element. A specific numbering definition instance in WordprocessingML can be divided into two parts:

- An abstract numbering reference
- (Optional) level overrides

The definition of all numbering definition instance properties can be found on the reference for the num element.

The required piece of information in a numbering definition instance, the instance must reference an abstract numbering definition using the abstractNumId element. This element specifies the value of the abstractNumId attribute for the inherited abstract numbering definition information.

Consider the WordprocessingML for a document with four numbering definition instances, two of which reference the same underlying abstract numbering definition:

```
<w:numbering>
  ...
  <w:num w:numId="2">
    <w:abstractNumId w:val="0" />
  </w:num>
  <w:num w:numId="3">
    <w:abstractNumId w:val="1" />
  </w:num>
```

```
    <w:num w:numId="4">
      <w:abstractNumId w:val="4" />
    </w:num>
    <w:num w:numId="5">
      <w:abstractNumId w:val="4" />
    </w:num>
  </w:numbering>
```

As shown above, the first two numbering definition instances reference abstractNumId values of 0 and 1 respectively, and the last two both reference the abstract numbering definition with an abstractNumId of 4.

The second (and optional) piece of information for a numbering definition instance is one or more numbering level overrides using the lvlOverride element. This element specifies a set of optional overrides applied to zero or more levels from the abstract numbering definition inherited by this instance.

Consider a numbering definition instance that inherits its information from the abstract numbering definition with abstractNumId of 4, but wishes to use a different set of properties for level 0 of the numbering definition. The resulting WordprocessingML would look like:

```
  <w:num w:numId="6">
    <w:abstractNumId w:val="4" />
    <w:lvlOverride w:ilvl="0">
      <w:lvl w:ilvl="0">
        <w:start w:val="4" />
        <w:lvlText w:val="%1)" />
        <w:lvlJc w:val="left" />
        <w:pPr>
          <w:ind w:left="360" w:hanging="360" />
        </w:pPr>
      </w:lvl>
    </w:lvlOverride>
  </w:num>
```

This level overrides level 0 of the list with the specified set of numbering properties, replacing those in the abtract numbering definition.

2.10.5 Applying Numbering to Paragraphs

Once numbering information is defined in the numbering part, this information must be associated with paragraphs within the document in order to display numbering on one or more paragraphs of content.

To accomplish this, numbered paragraphs are identified by the numPr element within the paragraph's properties element (the pPr element). The numbering properties within a paragraph are specified using two specific elements that specify the numbering definition information to use:

- A numbering definition instance reference

- A numbering level reference

The numbering definition instance reference is specified using the numId element. This element contains a reference to the numId attribute in a specific numbering definition instance within the numbering part, which links this paragraph to that numbering definition instance.

The numbering level reference is specified using the ilvl element. This element contains a reference to the ilvl attribute in the specified numbering definition instance's level information, which specifies the numbering level within the referenced numbering definition instance to be used by this numbered paragraph.

Consider the following numbered paragraphs in a WordprocessingML document:

1. Level one item one
    a. Level two item one
2. Level one item two
    a. Level two item one

These four numbered paragraphs, all referencing the same numbering definition, produce the following WordprocessingML:

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Level one item one</w:t>
  </w:r>
</w:p>
```

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="1" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Level two item one</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Level one item two</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="1" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Level two item one</w:t>
  </w:r>
</w:p>
```

In these numbered paragraphs, level 0 and 1 of the numbering definition are referenced through the ilvl element with a val attribute of `0` or `1`, respectively, however, the numId element always references the numbering definition instance with a val of `5`.

The numbering at any particular numbering level is restarted when a paragraph in the current document from the same numbering definition uses the level specified in the lvlRestart element for this numbering level.

Consider a set of numbered paragraphs in a WordprocessingML document where:

- Level 1 is set to restart after each level 0 (lvlRestart of 1)

- Level 2 is set to never restart (lvlRestart of 0)

1) Level one
    a) Level two – restarts after each level one
        i) Level three – never restarts
    b) Level two – restarts after each level one
        ii) Level three – never restarts
2) Level one
    a) Level two – restarts after each level one
        iii) Level three – never restarts
    b) Level two – restarts after each level one
        iv) Level three – never restarts

As the example shows, the numbering at level 1 (a, b, c, and so on) restarts after each level 0 is used, but level 2 (i, ii, iii, and so on) never restarts.

2.10.6 The Complete Story

To summarize the use of numbering information in a document, the paragraph properties specify a numPr element, which references a numbering definition instance via the numId element. The numbering definition instance specifies an inherited abstract numbering definition via the abstractNumId element. The paragraph then also specifies the list level from the numbering definition instance using the ilvl element.

Consider the following WordprocessingML for a numbered paragraph:

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="5" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>Numbered paragraph</w:t>
  </w:r>
</w:p>
```

Based on the numId of 5, the paragraph uses the numbering definition instance with a numId of 5:

```
<w:numbering>
  ...
  <w:num w:numId="5">
    <w:abstractNumId w:val="4" />
  </w:num>
</w:numbering>
```

Based on the abstractNumId of 4, this instance inherits the abstract numbering definition with an abstractNumId of 4:

```
<w:numbering>
  <w:abstractNum w:abstractNumId="4">
    <w:nsid w:val="FFFFFF7F" />
    <w:multiLevelType w:val="singleLevel" />
    <w:lvl w:ilvl="0">
      <w:start w:val="1" />
      <w:lvlText w:val="%1." />
      <w:lvlJc w:val="left" />
      <w:pPr>
        <w:tabs>
          <w:tab w:val="num" w:pos="720" />
        </w:tabs>
        <w:ind w:left="720" w:hanging="360" />
      </w:pPr>
    </w:lvl>
  </w:abstractNum>
  …
</w:numbering>
```

Since the numbering definition instance does not specify an override for ilvl 0, the definition for the corresponding level from the abstract numbering definition is applied to the text.

2.10.7 Numbering Styles

As stated earlier in the styles subclause (§2.8), numbering styles are style definitions which specify common formatting properties for a multi-level numbering format within a document. This means that a numbering style definition in the styles part defines only a single property: a reference to a numbering definition instance stored in the document's numbering part, using the numId element within the numPr element. That numbering definition instance specifies an abstract numbering style, which contains the numbering level information for the numbering style. It also specifies that it is the basis for the numbering style by back-referencing the numbering style's styleId attribute via the styleLink element.

Unlike paragraph and character styles, numbering styles are never directly referenced by content in the document—instead, an abstract numbering definition specifies that it contains the underlying numbering

information for a numbering style, and one or more numbering definition instances reference that abstract numbering definition.

2.10.8 Referencing Numbering Styles

To use a numbering style in a document, the paragraph properties for one or more paragraphs again specify a numPr element, which references a numbering definition instance via the numId element. The numbering definition instance itself again specifies an inherited abstract numbering definition via the abstractNumId element.

At this stage, the abstract numbering definition specifies that it is based on a numbering style via either of the following:

- The abstract numbering style contains no level data, and simply specifies a reference to the numbering style's styleId attribute via the numStyleLink element.
- The abstract numbering style contains the numbering level information for the numbering style, and specifies that it is the basis for the numbering style by referencing the numbering style's styleId attribute via the styleLink element.

Although the result of each method is identical, the following two examples illustrate each of the syntaxes:

Consider the first numbering style syntax, in which the numbering on a paragraph is based on an abstract numbering definition which simply references the numbering style via numStyleLink. The contents of the paragraph would consist of the following:

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="6" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>This paragraph references a numbering style via numStyleLink.</w:t>
  </w:r>
</w:p>
```

The numId element references a numbering definition instance with a value of 6, located in the numbering part:

```
<w:num w:numId="6">
  <w:abstractNumId w:val="0" />
</w:num>
```

Based on the abstractNumId of 0, this instance inherits the abstract numbering definition with an abstractNumId of 0:

```
<w:abstractNum w:abstractNumId="0">
  <w:nsid w:val="38901FA4" />
  <w:multiLevelType w:val="multilevel" />
  <w:numStyleLink w:val="TestNumberingStyle" />
</w:abstractNum>
```

This abstract numbering definition contains no numbering information - it simply notes that it inherits the numbering information from the numbering style `TestNumberingStyle` by referencing the styleId attribute on that style:

```
<w:style w:type="numbering" w:styleId="TestNumberingStyle">
  <w:name w:val="Test Numbering Style" />
  <w:uiPriority w:val="99" />
  <w:rsid w:val="00DB3C4B" />
  <w:pPr>
    <w:numPr>
      <w:numId w:val="4" />
    </w:numPr>
  </w:pPr>
</w:style>
```

The style references a numbering definition instance, again via the numId element:

```
<w:num w:numId="4">
  <w:abstractNumId w:val="2" />
</w:num>
```

Based on the abstractNumId of 2, this instance inherits the abstract numbering definition with an abstractNumId of 2:

```
<w:abstractNum w:abstractNumId="2">
  <w:nsid w:val="46364EB7" />
  <w:multiLevelType w:val="multilevel" />
  <w:styleLink w:val="TestNumberingStyle" />
  <w:lvl w:ilvl="0">
    <w:lvlText w:val="%1 %1 %1" />
    <w:lvlJc w:val="left" />
    <w:pPr>
      <w:tabs>
        <w:tab w:val="num" w:pos="360" />
      </w:tabs>
      <w:ind w:left="0" w:firstLine="0" />
    </w:pPr>
  </w:lvl>
  …
</w:abstractNum>
```

This abstract numbering definition defines the properties for each level of the numbering format (levels 1 through 9 omitted for brevity). Since neither of the numbering definition instances specified overrides for level 0, the properties from abstract numbering format 2 are applied to level 0 in the resulting numbering definition instance and are applied to the text via the ilvl element.

Consider the second numbering style syntax, in which the numbering on a paragraph is based on an abstract numbering definition which defines the numbering information and references the numbering style via styleLink. The contents of the paragraph would consist of the following:

```
<w:p>
  <w:pPr>
    <w:numPr>
      <w:ilvl w:val="0" />
      <w:numId w:val="4" />
    </w:numPr>
  </w:pPr>
  <w:r>
    <w:t>This paragraph references a numbering style via styleLink.</w:t>
  </w:r>
</w:p>
```

The numId element references a numbering definition instance with a value of 4, located in the numbering part:

```
<w:num w:numId="4">
  <w:abstractNumId w:val="2" />
</w:num>
```

Based on the abstractNumId of 2, this instance inherits the abstract numbering definition with an abstractNumId of 2:

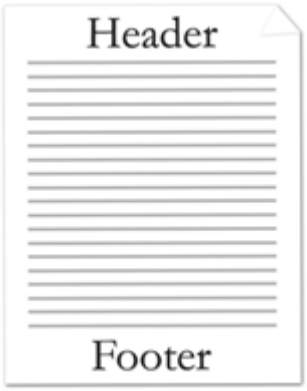
```
<w:abstractNum w:abstractNumId="2">
  <w:nsid w:val="46364EB7" />
  <w:multiLevelType w:val="multilevel" />
  <w:styleLink w:val="TestNumberingStyle" />
  <w:lvl w:ilvl="0">
    <w:lvlText w:val="%1 %1 %1" />
    <w:lvlJc w:val="left" />
    <w:pPr>
      <w:tabs>
        <w:tab w:val="num" w:pos="360" />
      </w:tabs>
      <w:ind w:left="0" w:firstLine="0" />
    </w:pPr>
  </w:lvl>
  …
</w:abstractNum>
```

This abstract numbering definition defines the properties for each level of the numbering format (levels 1 through 9 omitted for brevity) and specifies that it is the underlying numbering information for a numbering format by referencing the styleId of that numbering style via the styleLink element. Since the numbering definition instances specified no override for level 0, the properties from abstract numbering format 2 are applied to level 0 in the resulting numbering definition instance and are applied to the text via the ilvl element.

2.11 Headers and Footers

Headers and *footers* refer to text, graphics, or data (such as page number, date, document title, and so on) that can appear at the top or bottom of each page in a WordprocessingML document.

A *header* appears in the top margin (above the main document content on the page), while a *footer* appears in the bottom margin of a document page (below the main document content on the page); for example:



Since WordprocessingML is a flow-based format, headers and footers are applied by specifying the headers and footers for all pages in a particular section of a document.

2.11.1 Header Part

Header information in a WordprocessingML document is stored in a header part within the package, which is stored via an implicit relationship from the Main Document part or the Glossary Document part of relationship type `http://schemas.openxmlformats.org/wordprocessingml/2006/header` and has a content type of `vnd-openxmlformats.officedocument.wordprocessingml-header+xml`.

2.11.2 Footer Part

Footer information in a WordprocessingML document is stored in a footer part within the package, which is stored via an implicit relationship from the Main Document part or the Glossary Document part of relationship type `http://schemas.openxmlformats.org/wordprocessingml/2006/footer` and has a content type of `vnd-openxmlformats.officedocument.wordprocessingml-footer+xml`.

2.11.3 Headers and Footers

As described above, header and footer information is stored in one or more header or footer parts within the package.

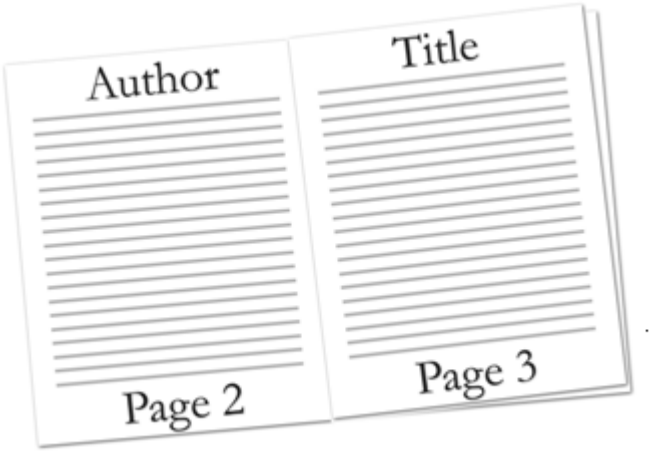
The hdr element defines a single header for the document, while the ftr element defines a single footer for the document. Headers and footers are just another document story in WordprocessingML. Within the root element of the header or footer, the content of the element is similar to the content of the body element, and contains what is referred to as *block-level markup* —markup that can exist as a sibling element to paragraphs in a WordprocessingML document.

Within each section of a document there can be up to three different types of headers and footers:

- First page header/footer
- Odd page header/footer
- Even page header/footer

First page headers and *footers* specify a unique header or footer that shall appear on the first page of a section. *Odd page headers* and *footers* specify a unique header and footer that shall appear on all odd numbered pages for a given section. *Even page headers* and *footers* specify a unique header and footer that shall appear on all even numbered pages in a given section.

Different headers or footers can be useful for bounded documents like books, as shown in the figure below.



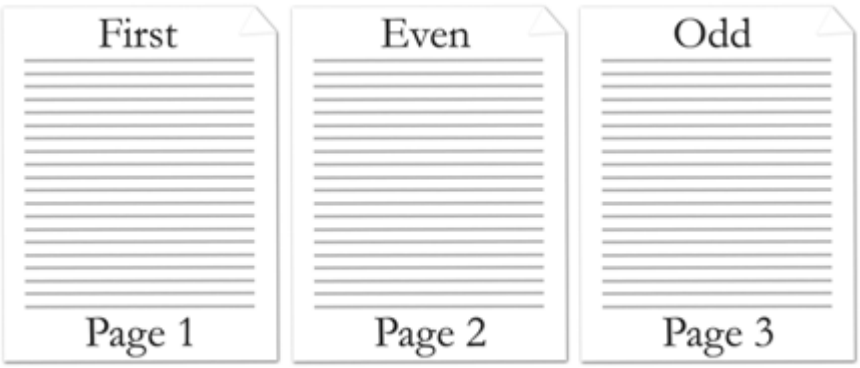
Consider the following simple one-page document with one header:

This document defines one header with the text `Header`. The header's content is stored in a unique Header part. The resulting header is represented by the following WordprocessingML:

```
<w:hdr>
  <w:p>
    <w:r>
      <w:t>Header</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

Since headers are containers of block level contents, all block level contents can be used within them. In this particular example, the content is a single paragraph.

Consider a more complex three-page document with different first, odd, and even page headers defined:



This document defines three headers stored in three different header parts. The resulting headers are represented by the following WordprocessingML:

First page header part:

```
<w:hdr>
  <w:p>
    <w:r>
      <w:t>First</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

Even page header part:

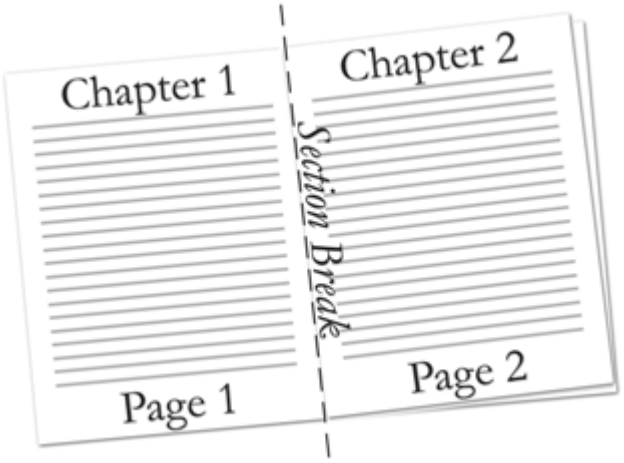
```
<w:hdr>
  <w:p>
    <w:r>
      <w:t>Even</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

Odd page header part:

```
<w:hdr>
  <w:p>
    <w:r>
      <w:t>Odd</w:t>
    </w:r>
  </w:p>
</w:hdr>
```

2.11.4 Multiple Sections

Documents are capable of having multiple sections, where each section can define up to three headers and footers. By default, sections other than the first section inherit the previous header and footer references, unless that section specifies header and footer references.



Consider a two-page, two-section document with only the first section header defined. This document defines one header that is referenced in the first section. The document is represented by the following WordprocessingML:

```
<w:body>
  …
  <w:p>
    <w:pPr>
      <w:sectPr>
        <w:headerReference r:id="rId6" />
        …
      </w:sectPr>
    </w:pPr>
    …
  </w:p>
  …
  <w:sectPr>
    …
  </w:sectPr>
</w:body>
```

The second section does not explicitly reference a header. Instead, the second section inherits the header from the previous section.

2.11.5 Empty Header or Footer

Not specifying a header and footer reference in a section, other than the first section, causes the document to inherit the previous section's header and footer references. In order to declare an empty header or footer, a header or footer reference must be made to a null header or footer relationship, as follows:

```
<Relationship Id="rId2" Type="http:// …/header" Target="null" />
```

The `null` attribute value specifies that the header or footer shall not be inherited from the previous section, and a blank header or footer shall explicitly be used.

2.12 Footnotes and Endnotes

Footnotes and *endnotes* are separate text stories used in documents and books to show the source of borrowed material or to enter explanatory or supplementary information that does not interrupt the normal reading flow of the document.

Footnotes are typically located at the bottom of a page or beneath text being referenced, and *endnotes* are typically placed at the end of a document or at the end of a section. If document has been divided up into one or more sections, each section of a document can contain endnotes.

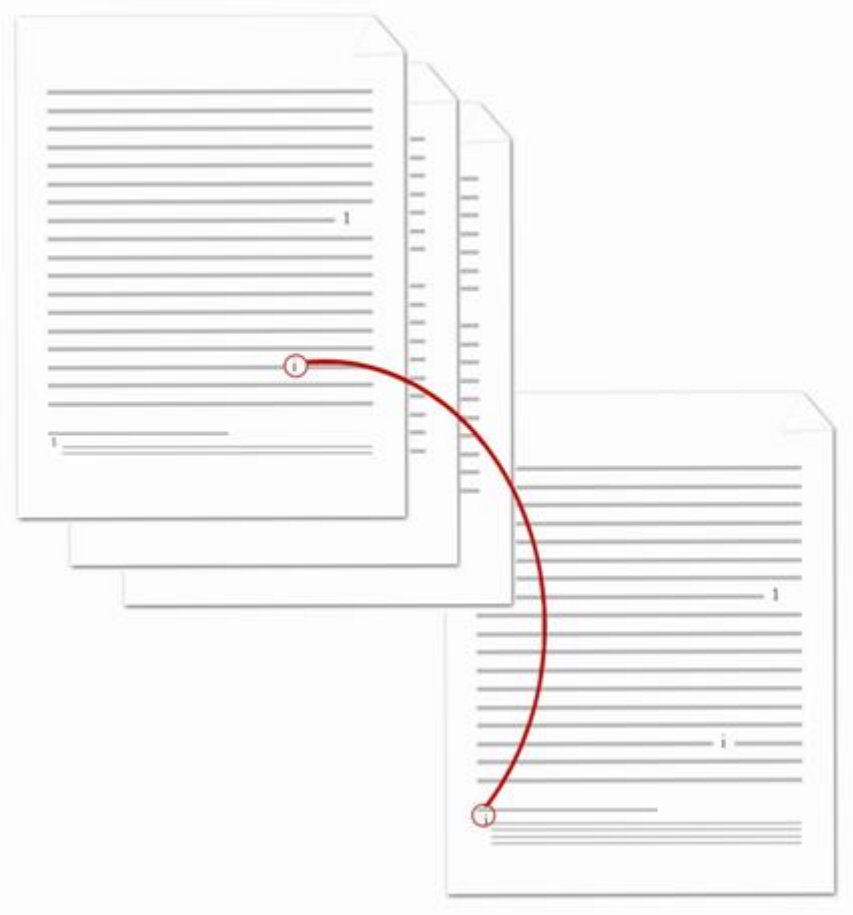
Both footnotes and endnotes consist of two parts:

- A note reference mark in the body text to indicate that additional information is in a footnote or endnote, with a numbering system used for each to tell readers whether to look for the note at the end of the page or the end of the document or section.
- The actual footnote or endnote story content.

Here's an example of a footnote applied to text in a document:

The note reference mark follows the noted text and specifies that there is associated footnote information; the footnote itself is at the bottom of the current page.

Consider the following example of an endnote applied to text in a document:



The note reference mark follows the noted text and specifies that there is associated endnote information; the endnote itself is at the end of the current section.

2.12.1 Footnote Part

Footnote information in a WordprocessingML document is stored in the footnotes part within the package, which is stored via an implicit relationship from the Main Document part or Glossary Document part of relationship type `http://schemas.openxmlformats.org/wordprocessingml/2006/footnotes` and has a content type of `vnd-openxmlformats.officedocument.wordprocessingml-footnotes+xml`.

2.12.2 Endnote Part

Endnote information in a WordprocessingML document is stored in the Endnotes part within the package, which is stored via an implicit relationship from the Main Document part or Glossary Document part of

relationship type `http://schemas.openxmlformats.org/wordprocessingml/2006/endnotes` and has a content type of `vnd-openxmlformats.officedocument.wordprocessingml-endnotes+xml`.

2.12.3 Footnotes and Endnotes

As described above, footnote and endnote information is stored in the corresponding footnotes and endnotes part within the package. The footnotes element below specifies three or more footnotes, each identified by the footnote element, for the document. The endnotes element specifies three or more endnotes, each identified by the endnote element, for the document. Each footnote or endnote element is associated with a unique ID, specified by the attribute id.

Consider three different types of footnotes, each identified by a footnote element, defined in the Footnotes part. The use of each type of footnote is defined in the next subclause:

```
<w:footnotes ...>
  <w:footnote w:type="separator" w:id="0">
    …
  </w:footnote>
  <w:footnote w:type="continuationSeparator" w:id="1">
    …
  </w:footnote>
  <w:footnote w:id="2">
    …
  </w:footnote>
</w:footnotes>
```

Similarly consider three different types of endnotes, each identified by an endnote element, defined in the Endnotes part. The use of each type of endnote is defined in the next subclause:

```
<w:endnotes ...>
  <w:endnote w:type="separator" w:id="0">
    …
  </w:endnote>
  <w:endnote w:type="continuationSeparator" w:id="1">
    …
  </w:endnote>
  <w:endnote w:id="2">
    …
  </w:endnote>
</w:endnotes>
```

Footnotes and endnotes are just another kind of paragraph in WordprocessingML. Within the footnote or endnote element, the footnote or endnote may contain any valid block-level content.

2.12.4 Footnote and Endnote Types

There are four different types of footnotes and endnotes:

- Normal – contain the text of any footnote (or endnote) in the document.
- Separator – define the separator used to separate the footnote (or endnote) from the document text.
- Continuation separator – define the separator used to separate the footnote (or endnote) from the document text when the footnote or endnote is a continuation from the previous page.
- Continuation notice – define the notice text to let readers know that the footnote (or endnote) has continued on the next page.

The attribute type specifies the type of footnote or endnote. Normal footnotes or endnotes are specified by a type of `normal` or by omitting type. In conjunction to a `normal` type, a footnote reference mark, specified by footnoteRef element, or endnote reference mark, specified by endnoteRef element, must be present within the footnote or endnote definition.

Consider the following page in a document, where some text is referenced by a footnote at the end of a page:

The footnote text at the bottom of the page is a normal type footnote represented by the following WordprocessingML:

```
<w:footnote w:id="2">
  <w:p>
    <w:pPr>
      <w:pStyle w:val="FootnoteText" />
    </w:pPr>
```

```
      <w:r>
        <w:rPr>
          <w:rStyle w:val="FootnoteReference" />
        </w:rPr>
        <w:footnoteRef />
      </w:r>
      <w:r>
        <w:t>Cool reference</w:t>
      </w:r>
    </w:p>
  </w:footnote>
```

Not specifying any type attribute in the footnote element defaults to being a `normal` type of footnote. In this example, the footnote has a unique ID of 2. The text of the footnote is contained in the text run. Like any paragraph, footnotes can be associated with a particular style, and, in this example, the paragraph uses the `FootnoteText` paragraph style. Similarly, like any run, footnotes can be associated with a particular style, and, in this example, the run uses the `FootnoteReference` run style.

Separator footnotes or endnotes are specified by `separator`. These types of footnotes or endnotes define the look of the separator used to separate document text from footnotes or endnotes. In conjunction to `separator` type, a footnote or endnote separator reference mark, specified by a separator element must be present within the footnote or endnote definition.

Consider the following page in a document, where some text is referenced by a footnote at the end of a page:

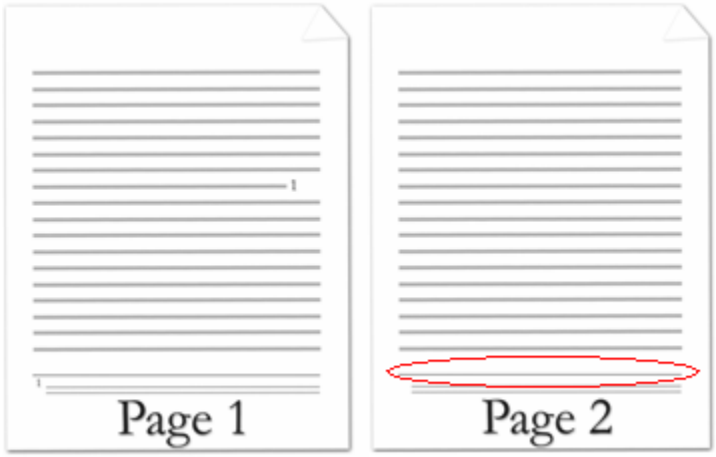
The line separating the document text from the footnote is represented by the following WordprocessingML:

```
<w:footnote w:type="separator" w:id="0">
  <w:p>
    <w:pPr>
      <w:spacing w:after="0" w:line="240" w:lineRule="auto" />
    </w:pPr>
    <w:r>
      <w:separator />
    </w:r>
  </w:p>
</w:footnote>
```

In this example, the footnote has a unique ID of `0`. The vertical spacing after the line separator is 0 twentieths of a point. The vertical spacing between the line separator and text is 240 twentieths of a point.

Continuation separator footnotes or endnotes are specified by `continuationSeparator`. These types of footnotes or endnotes define the look of the separator used to separate document text from footnotes or endnotes when the footnote or endnote continues the next page. In conjunction to a `continuationSeparator` type, a footnote or endnote continuation separator reference mark, specified by continuationSeparator element must be present within the footnote or endnote definition.

Consider the following two pages in a document, where some text is referenced by a footnote that extends to the next page:



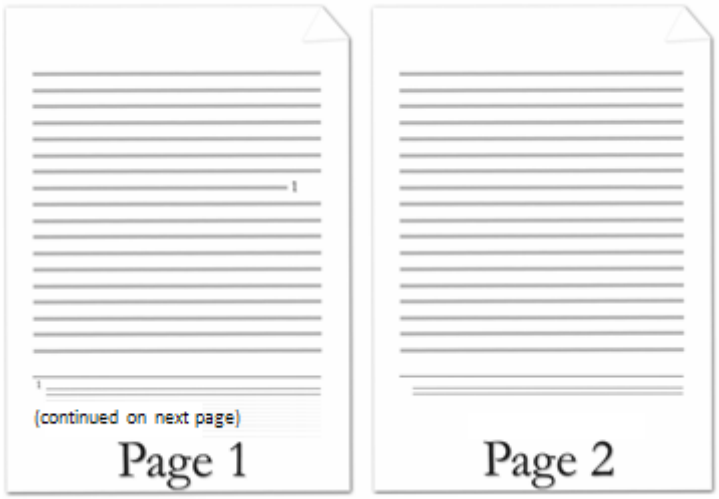
The line separating the document text from the footnote that is continued on the next page (circled in red in the image above) is the continuation separator footnote, and is represented by the following WordprocessingML:

```
<w:footnote w:type="continuationSeparator" w:id="1">
  <w:p >
    <w:pPr>
      <w:spacing w:after="0" w:line="240" w:lineRule="auto" />
    </w:pPr>
    <w:r>
      <w:continuationSeparator />
    </w:r>
  </w:p>
</w:footnote>
```

In this example, the footnote has a unique ID of 1. The vertical spacing after the line separator is 0 twentieths of a point. The vertical spacing between the line separator and text is 240 twentieths of a point.

Continuation notice footnotes or endnotes are specified by `continuationNotice`. These types of footnotes or endnotes specify the text to let readers know that the footnote or endnote is continued on the next page.

Consider the following two pages in a document, where some text is referenced by a footnote that extends to the next page. A continuation notice is given to readers to indicate that the footnote extends to the next page:



The continuation notice text is at the bottom of the footnote indicating that the footnote is continued to the next page (which reads `continued on next page above`) and is represented by the following WordprocessingML:

```
<w:footnote w:type="continuationNotice" w:id="3">
  <w:p >
    <w:pPr>
      <w:spacing w:after="0" w:line="240" w:lineRule="auto" />
    </w:pPr>
```

```
        <w:r>
          <w:t>(continued on next page)</w:t>
        </w:r>
      </w:p>
    </w:footnote>
```

In this example, the footnote has a unique ID of 3. The text that shows up after the footnote text is `(continued on next page)`.

2.12.5 Footnote and Endnote Reference

Once footnote or endnote information is defined in the footnotes or endnotes part, this information must be associated with document text within the document in order to display the footnotes or endnotes. Each footnote or endnote is identified by a unique ID that references footnote or endnote definitions specified in the footnotes or endnotes part. Footnote or endnote references are identified by the footnoteReference or endnoteReference element within the text run's element (the r element). The footnoteReference or endnoteReference element points to the footnote or endnote ID defined in the footnotes or endnotes part.

Consider the following one-page document, where some text is referenced by a footnote at the end of the document page:

The footnote references text and is represented by the following WordprocessingML:

```
    <w:p>
      <w:r>
        <w:t>Some referenced text</w:t>
      </w:r>
```

```
    <w:r>
      <w:rPr>
        <w:rStyle w:val="FootnoteReference" />
      </w:rPr>
      <w:footnoteReference w:id="2" />
    </w:r>
  </w:p>
```

The footnote references the footnote in the footnotes part with ID equals to 2. Like any run, footnotes can be associated with a particular style, and, in this example, the run uses the `FootnoteReference` run style. The style of the footnote defines the look and numbering of the footnote.

2.13 Glossary Document

The introduction to a WordprocessingML document formally introduced the concept of stories, individual ranges of a word-processing document containing block-level content like paragraphs and tables. Some examples of stories in a WordprocessingML document include the following: the main document, headers, footers, comments, footnotes, and endnotes.

At that time, a story was defined by two characteristics:

- It is a unique region containing block-level content
- All document stories shared the same set of properties (e.g., style definitions, numbering definitions, and settings)

The glossary document, although it follows the first rule, actually defies the second.

Within a WordprocessingML file, the *glossary document* is a supplemental storage location for additional document content which shall travel with the document, but which shall not be displayed for printed as part of the main document until it is explicitly added to that document by deliberate action.

The glossary document shall also be afforded a separate instance of all of the relationships that are provided on the main document part - this means that the glossary document shall have its own style definitions, numbering definitions, comments, headers, footers, etc. within the WordprocessingML document.

Consider a document that shall include ten optional clauses that may be inserted through a user interface. It is clearly not desirable to have these ten clauses appear in the main document story's contents before they are explicitly inserted, therefore each of them may be stored in the glossary document and inserted via the user interface as needed.

Within the glossary document, each distinct region of document content is referred to as a *glossary document entry*, and is defined via the docPart element. These document parts may contain any block-level WordprocessingML element, and may also have a set of classifications and behaviors applied to them via the glossary document entry's properties.

Consider the following definition for the contents of a glossary document part within a WordprocessingML document:

```
<w:glossaryDocument>
  <w:docParts>
    <w:docPart>
      <w:docPartPr>
        …
      </w:docPartPr>
      <w:docPartBody>
        <w:p>
          <w:r>
            <w:t>Sample entry.</w:t>
          </w:r>
        </w:p>
      </w:docPartBody>
    </w:docPart>
    <w:docPart>
      …
    </w:docPart>
  </w:docParts>
</w:glossaryDocument>
```

The glossaryDocument element defines the contents of the glossary document part. Within the glossary document, each docPart element contains the definition for one glossary document entry: in this case, there are two entries in the glossary document, the first of which contains a single paragraph with a single run of text.

Each glossary document entry consists of two components:

- The entry's properties, specified using the docPartPr element
- The entry's contents, specified using the docPartBody element

The first specifies information about the entry (e.g., its classification) for when it is inserted, the latter stores the block level content which constitutes the entry.

2.14 Annotations

2.14.1 Introduction

An *annotation* is one of various kinds of supplementary markup, which may be stored inside or around a region of text within the document's contents. The kinds of supplementary information stored within a document can include comments (§2.14.5), revisions (§2.14.7), spelling and/or grammatical errors (§2.14.10), bookmark information (§2.14.8), and optional editing permissions (§2.14.9).

Within a document's contents, annotations are stored in one of three different forms:

- Inline
- Cross-Structure
- Properties

These three forms are needed in order to maintain compatibility with both the legacy annotations functionality of current word-processing applications and the requirements of an XML-based format (i.e., well-formedness of the resulting XML markup). These three forms are referenced within the individual annotation types described in subclauses §2.14.2 through §2.14.4.

2.14.2 Inline Annotations

An *inline annotation* is a form of annotation that does not require special handling in order to maintain the XML well-formedness requirements of the resulting WordprocessingML output. In these cases, a single XML element shall encapsulate the entire contents of the document content which is being annotated.

Consider the following WordprocessingML markup for a paragraph that reads `The quick brown fox jumps over the jet lagged dog.`, where `jet lagged` replaced the previous text `lazy` when the editing application was tracking revisions:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">The quick brown fox jumps over the </w:t>
  </w:r>
  <w:del … >
    <w:r>
      <w:delText>lazy</w:delText>
    </w:r>
  </w:del>
  <w:ins … >
    <w:r>
      <w:t>jet lagged</w:t>
    </w:r>
  </w:ins>
  <w:r>
    <w:t xml:space="preserve"> dog.</w:t>
  </w:r>
</w:p>
```

The del and ins elements each fully encapsulate the extent of their respective annotations (a marked deletion and insertion, respectively), as they are inline annotations.

2.14.3 Cross-Structure Annotations

A *cross-structure annotation* is a form of annotation that can span portions of WordprocessingML markup. (Cross-structure annotations may span parts of multiple paragraphs, one half of a custom XML markup element's contents, and so on.) In these cases, the annotation's region is delimited by two elements, a start

element and an end element, which mark the start and end points of the annotated content, respectively, but do not contain it. Matching start and end markers have the same id attribute value.

Consider the following WordprocessingML markup for two paragraphs, each reading `Example Text`, where a bookmark has been added spanning the second word in paragraph one, and the first word in paragraph two:

```
<w:p>
  <w:r>
    <w:t>Example</w:t>
  </w:r>
  <w:bookmarkStart w:id="0" w:name="sampleBookmark" />
  <w:r>
    <w:t xml:space="preserve"> text.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:r>
    <w:t>Example</w:t>
  </w:r>
  <w:bookmarkEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve"> text.</w:t>
  </w:r>
</w:p>
```

The bookmarkStart and bookmarkEnd elements specify the location where the bookmark starts and ends, but cannot contain that bookmark because it spans parts of two paragraphs. They are part of one group because the id attribute value specifies `0` for both.

2.14.4 Property Annotations

A *property annotation* is a form of annotation that is stored as a property on an object (Property annotations may appear on paragraph properties, run properties, table rows, and so on.) In these cases, the annotation's semantics are defined by the property, as they can affect content and/or formatting.

Consider the following WordprocessingML markup for a paragraph reading `Example Text`, where the first word had the bold property applied when the editing application was tracking revisions:

```
<w:p>
  <w:r>
    <w:rPr>
      <w:b/>
      <w:rPrChange … >
        <w:rPr/>
      </w:rPrChange>
    </w:rPr>
    <w:t>Example</w:t>
  </w:r>
  <w:r>
    <w:t xml:space="preserve"> text.</w:t>
  </w:r>
</w:p>
```

The rPrChange element contains the set of previously applied revision properties associated with a particular author at a particular time. It is stored itself as a property on the parent run which was modified.

2.14.5 Comments

A *comment* is an annotation that is anchored to a region of document content, but which contains an arbitrary amount of block-level content stored in its own separate document story. Within a WordprocessingML document, comments are stored in a separate comments part within the document package.

A comment in a WordprocessingML document is divided into two components:

- The comment anchor (the text to which the comment applies)
- The comment content (the contents of the comment)

The *comment anchor* is the cross-structure annotation that defines the region of text on which the comment in anchored. The *comment content* is the text of the comment.

Consider a paragraph in a WordprocessingML document whose second word is annotated with a comment:

The first component to this comment is the document content, which defines the extents of the comment and references the specific comment in the comments part:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">Some </w:t>
  </w:r>
```

```
    <w:commentRangeStart w:id="0" />
    <w:r>
      <w:t>text.</w:t>
    </w:r>
    <w:commentRangeEnd w:id="0" />
    <w:r>
      <w:commentReference w:id="0" />
    </w:r>
  </w:p>
```

The commentRangeStart and commentRangeEnd elements delimit the run content to which the comment with an id of `0` applies (in this case, the single run of text). The commentReference element that follows links the preceding run content with a comment in the comments part having an id of `0`. Without all three of these elements, the range and comment cannot be linked (although the first two elements are optional, in which case the comment shall be anchored at the comment reference mark)

The second component to this comment is the comment content, which defines the text in the comment:

```
  <w:comment w:id="0" w:author="Joe Smith"
    w:date="2006-04-06T13:50:00Z" w:initials="User">
    <w:p>
      <w:pPr>
        <w:pStyle w:val="CommentText" />
      </w:pPr>
      <w:r>
        <w:rPr>
          <w:rStyle w:val="CommentReference" />
        </w:rPr>
        <w:annotationRef />
      </w:r>
      <w:r>
        <w:t>comment</w:t>
      </w:r>
    </w:p>
  </w:comment>
```

In this example, the comment specifies that it was inserted by author `Joe Smith` with the initials `User` via the author and date attributes. It is linked to the run content via the id attribute, which matches the value of `0` specified using the commentReference element above. The block-level content of the comment specifies that its text is comment and the style of the comment content is based off of the character style with the name `CommentReference`.

2.14.6 Comments Part

Comment information in a WordprocessingML document is stored in the Comments part within the package, which is stored via an implicit relationship from the Main Document or Glossary Document part of relationship type `http://…/comments` and has a content type of `vnd-openxmlformats.officedocument.wordprocessingml-comments+xml`.

2.14.7 Revisions

A *revision* provides a mechanism for storing information about the evolution of the document (i.e., the set of modifications made to a document by one of more authors). When an application adds revisions to the content of a WordprocessingML document, depending on the revision type they are specifying this by storing either:

- The current state of the document (a deletion stores the current state of the text as deleted, and implies that its original state was the content that used to exist)
- The initial state of the document (a run's initial properties are explicitly stored in a previous run properties block, as the current run properties are always those that are the child of the rPr element

A revision consists of two required pieces of information:

- The revision type (specified via the name of the revision element)
- A unique revision identifier (used to uniquely identify revisions)

As well as optional information:

- The author of the revision
- The date and time of the revision

A revision is stored using the inline annotation format or the property annotation format.

Consider a paragraph of text in a WordprocessingML document in which one word has been inserted, as follows:

This paragraph has the word `text` marked inserted as a revision, and is represented as the following WordprocessingML:

```
<w:p>
  <w:r>
    <w:t>Some</w:t>
  </w:r>
  <w:ins w:id="0" w:author="Joe Smith" w:date="2006-03-31T12:50:00Z">
    <w:r>
      <w:t>text</w:t>
```

```
      </w:r>
    </w:ins>
  </w:p>
```

The ins element contains all of the content that shall be treated as revision marked as inserted (i.e., the word `text`).

This means that it contains both required pieces of information: the revision type, specified by the name of the revision element (ins); and a unique revision identifier of `0`.

The element also stores the optional information about the revision: the word `text` was inserted by `Joe Smith` on March 31, 2006 at 12:50 pm.

Within a WordprocessingML document, the following types of revisions can be used to track the changes to a document (each annotation's form in parentheses):

- Insertions (inline annotations for run content, property annotations for tables and paragraphs)
- Deletions (inline annotations for run content, property annotations for tables and paragraphs)
- Moves (inline annotations)
- Changes to run/paragraph/table/numbering/section properties (property annotations)
- Changes to custom XML markup (property annotations)

2.14.8 Bookmarks

A *bookmark* refers to an arbitrary region of content that is bounded and has a unique name associated with it.

Because bookmarks are a legacy word-processing function that predates the concepts of XML and well-formedness, they can start and end at any location within a document's contents and, therefore, must use the cross-structure annotation format described in §2.14.3.

Consider the following WordprocessingML markup for two paragraphs, each reading `Example Text`, where a bookmark has been added spanning the second word in paragraph one and the first word in paragraph two:

```
  <w:p>
    <w:r>
      <w:t>Example</w:t>
    </w:r>
    <w:bookmarkStart w:id="0" w:name="sampleBookmark" />
    <w:r>
      <w:t xml:space="preserve"> text.</w:t>
    </w:r>
  </w:p>
```

```
<w:p>
  <w:r>
    <w:t>Example</w:t>
  </w:r>
  <w:bookmarkEnd w:id="0" />
  <w:r>
    <w:t xml:space="preserve"> text.</w:t>
  </w:r>
</w:p>
```

The bookmarkStart and bookmarkEnd elements specify the location where the bookmark starts and ends, but cannot contain it using a single tag because it spans parts of two paragraphs. However, the two tags are part of one group because the id attribute value specifies `0` for both.

2.14.9 Range Permissions

A *range permission* refers to a special type of bookmark used to control which subset(s) of users may edit a particular region of a document. Range permissions specify the user, or set of users, that are allowed to edit all content between them whenever the document protection specified by the documentProtection element is enabled and set to `readOnly` or `comments`.

Like bookmarks, range permissions are a legacy word-processing function that predates the concepts of XML and well-formedness, so they can start and end at any location within a document's contents and, therefore, must use the cross-structure annotation format described in §2.14.3.

Consider the following WordprocessingML markup for a single paragraph, where a range permission has been added spanning the words `range permission`:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">This is a </w:t>
  </w:r>
  <w:permStart w:id="0" w:edGrp="everyone"/>
  <w:r>
    <w:t>range permission</w:t>
  </w:r>
  <w:permEnd w:id="0"/>
  <w:r>
    <w:t>.</w:t>
  </w:r>
</w:p>
```

The permStart and permEnd elements specify the location where the range permission starts and ends. The two tags are part of one group because the id attribute value specifies `0` for both.

If document protection was enabled, then no content in this document shall be editable except for this range permission, which is editable by all users that open the document (specified using an editor group of everyone).

2.14.10 Spelling and Grammar

A *spelling and grammar error* is an annotation used to specify the locations of an existing spelling and/or grammatical error within the contents of a document. Spelling and grammar errors use the cross-structure annotation format.

Rationale: When a WordprocessingML document is saved, applications may choose to save currently flagged spelling and grammar errors, for two reasons:

- In order to increase the performance subsequent loads of the document (as those load operations can rely on the persisted proofing state of the document)
- In order to store words which shall not be marked as proofing errors regardless of how they would normally be flagged by the proofing tools engine (i.e., to store spelling and grammar exceptions).

Consider the following paragraph consisting of two misspelled words, where the second word has been explicitly flagged as not being a spelling error. This paragraph would consist of the following WordprocessingML markup:

```
<w:p>
  <w:proofErr w:val="spellStart"/>
  <w:r>
    <w:t>erqwt</w:t>
  </w:r>
  <w:proofErr w:val="spellEnd"/>
  <w:r>
    <w:t xml:space="preserve"> werewr</w:t>
  </w:r>
</w:p>
```

The proofErr elements, with a val attribute value of `spellStart` and `spellEnd`, respectively, delimit the start and end of the content in this paragraph that is stored as a spelling error. Since the second word is not included in that range, it is not stored as a spelling error.

2.15 Mail Merge

Mail merge refers to a process by which a WordprocessingML document is connected to and populated with external data by a conforming hosting application and/or data source access application. A WordprocessingML document that contains the necessary data to connect to an external data source during a Mail Merge is known as a source document. In other words, a source document is a WordprocessingML document containing the elements and attributes necessary to enable the document to connect to an external data source, but not yet merged with any data.

Applications leverage source documents to generate new documents containing the static content contained in the merged document as well as data from the specified external data source. The documents that result from importing external data into a source document are known as merged documents. How source documents and merged documents are specified is explained in the following sections.

2.15.1 Mail Merge, WordprocessingML, and Hosting Applications

The two key parts of the mail merge process are:

1. Connecting to an external data source
2. Populating mail merge fields with external data

It is important to note that aspects of the mail merge process outside of connecting to an external data source and populating mail merge fields with external data, are at the discretion of the hosting application.

As an additional example, WordprocessingML provides an element to be used as a flag by hosting applications to specify action to be taken on the merged documents that are generated by a mail merge. In other words, performing actions such as:

- creating a new document for each merged document
- generating and sending emails containing merged document
- printing merged documents

may be specified through WordprocessingML, but what if any specific action is taken on merged documents is determined by the application.

2.15.2 Connecting Documents to an External Data Source

As mentioned, a source document is the single WordprocessingML document that contains the data necessary to be connected to an external data source by a conforming hosting application and/or data source access application. The presence and parameters of this connection are specified within the mailMerge element. This element enables WordprocessingML documents to be connected to an external data source by specifying the following data:

- Where the external data is located (e.g., file path)
- What type of data the external data source contains (e.g., database and spreadsheet)
- How the data will be accessed

Consider a document containing static WordprocessingML constructs such as paragraphs in addition to two WordprocessingML mail merge fields calling for `Courtesy Title` and `Last Name` data.

Dear {MERGEFIELD "Courtesy Title" \m} {MERGEFIELD "Last Name" \m},

Sample text. Sample text.

Sincerely,

If the following WordprocessingML was added to this document, this document would become a source document rather than just a standard WordprocessingML document, as the mailMerge element specifies the elements and attributes necessary to enable the hosting applications and/or data source access applications to connect the document to an external data source.

```
<w:mailMerge>
  …
  <w:dataType w:val="database" />
  <w:query w:val="SELECT * FROM Table1" />
  <w:dataSource r:id="rId1" />
  …
</w:mailMerge>
```

Here, the dataType and dataSource elements specify that the given document shall be connected to the external data source referenced by the r:id attribute's value of `rId1`. While connected to the external data source, the merged document together with the hosting application and/or data source access application may extract data from the external data source as specified by the connectString and query elements.

2.15.3 Populating Merged Documents with External Data

Before the hosting application can populate merged documents with external data, mail merge fields must be inserted into the *merged* document and mapped to the external data. How external data is mapped to given mail merge fields is determined by the WordprocessingML element fieldMapData.

Consider the example merged document from the previous example which contained the two mail merge fields calling for `Courtesy Title` and `Last Name`. The WordprocessingML below demonstrates how mapping of the external data to the merged document's mail merge fields occurs:

```
<w:fieldMapData>
  <w:type w:val="dbColumn" />
  <w:name w:val="Customer Title" />
  <w:mappedName w:val="Courtesy Title" />
  <w:column w:val="9" />
</w:fieldMapData>
<w:fieldMapData>
  <w:type w:val="dbColumn" />
  <w:name w:val="Customer Last Name" />
  <w:mappedName w:val="Last Name" />
  <w:column w:val="10" />
</w:fieldMapData>
```

Within the first fieldMapData element, the child elements column, name, type, and mappedName specify that the data contained within tenth column titled 'Customer Title', in the specified external database, is to be mapped to the mail merge field calling for 'Courtesy Title' data, respectively. Within the second fieldMapData element, the child elements column, name, type, and mappedName specify that the data contained within eleventh column in the specified external database is to be mapped to the merge field titled `Customer Last Name` or the predefined merge field name `Last Name`.

Once a merged document's mail merge fields have been mapped to external data, the hosting application and/or data source access application may populate the respective fields with applicable external data.

Consider a conforming hosting application and/or data source access application that wishes to populate the mail merge fields within the merged document from the previous example with applicable external data. In addition, consider that the specified external data source contains two records--one for Mr. John Doe and one for Ms. Jane Smith. With external data from the `Customer Title` column mapped to the Mail Merge field calling for `Courtesy Title` data, and the `Customer Last Name` column mapped to the Mail Merge field calling for `Last Name` data to populate the fields within this merged document with external data.

The mail merge process will then run through the specified external database and populate the mail merge fields with the data from the `Customer Title` and `Customer Last Name` columns in the specified database, and generate two of merged documents containing the specified external data as well as the static contents of the source document (illustrated in the table below):

Source Document	Merged document populated with first external data source entry	Merged document populated with second external data source entry

Source Document	Merged document populated with first external data source entry	Merged document populated with second external data source entry
Dear{MERGEFIELD "Courtesy Title" \m} {MERGEFIELD "Last Name" \m}, Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sincerely,	Dear Mr. Doe: Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sincerely,	Dear Ms. Smith: Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sample text. Sincerely,

2.16 Settings

A *setting* specifies a stored preference that shall be used when processing the contents of the document. In other words, settings refer to specified behaviors that shall be applied to WordprocessingML documents on a document by document basis. Just like paragraphs and text runs have properties specified that apply to their contents, entire WordprocessingML documents leverage settings to specify properties and behaviors that apply to the entire document.

These settings are typically divided into three categories:

- *Document Settings* — Settings that influence the appearance and behavior of the current document, as well as storing document-level state.
- *Compatibility Settings* — Settings that tell applications to perform behaviors which are designed to maintain visual output of previous word-processing applications.
- *Web Settings* — Settings that affect how a document shall be handled when it is saved as HTML.

2.16.1 Document Settings

A *document setting* specifies a document-level property that affects the handling of a given document, and influences the appearance and behavior of the current document, as well as the stored document-level state. All document settings are found in the Document Settings part.

Consider a document in which the document setting doNotHyphenateCaps is applied. As a document setting this element specifies whether words comprised of all capitalized letters shall be hyphenated or not throughout the given document.. Specifically, if words in ALL CAPITAL LETTERS shall not be hyphenated, this requirement would be specified by adding the following WordprocessingML to the settings part:

```
<w:doNotHyphenateCaps w:val="true"/>
```

Specifying that words comprised of ALL CAPITAL LETTERS shall be hyphenated, as illustrated below:

THIS IS A HYPHENATION EXAMPLE. THIS IS A SHORT HYPHENATION EXAMPLE. THIS IS A SHORT HYPHENATION EXAMPLE.

If this element is omitted, then words in ALL CAPITAL LETTERS shall be hyphenated when the document is hyphenated, as illustrated below:

THIS IS A HYPHENATION EXAMPLE. THIS IS A SHORT HYPHENATION EXAMPLE. THIS IS A SHORT HYPHE-NATION EXAMPLE.

2.16.2 Compatibility Settings

A *compatibility setting* is an optional setting used to mimic behavior of documents created in earlier word-processing applications. It is recommended that new WordprocessingML documents contain no compatibility settings. If compatibility settings are needed, they are stored in the Document Settings part (§2.16.1).

Consider a document in which the compatibility setting ww11IndentRules is applied. As a compatibility setting, this element specifies an indentation behavior to be applied throughout the given document to preserve visual fidelity with an earlier word processing application. Specifically, if the indentation applied to numbering when positioned next to a wrapped object shall not be suppressed, this requirement would be specified by adding the following WordprocessingML to the settings part

```
<w:compat>
  <w:ww11IndentRules />
</w:compat>
```

Specifying that indentation applied to numbering when positioned next to a wrapped object shall not be suppressed, as illustrated below:

1. Example

2. Example
3. Example
4. Example
5. Example

If this element is omitted, then indentation applied to numbering when positioned next to a wrapped object shall be suppressed, as illustrated below:

1. Example

2. Example
3. Example
4. Example
5. Example

2.16.3 Web Settings

A *web setting* is a setting used to specify a document-level property that is applicable when saving a web page as a WordprocessingML document, or when saving a WordprocessingML document as a webpage. Thus, if a given WordprocessingML document was not created from a web page, and will never become a web page, no web settings are needed within the document. If they are needed, web settings are stored in the Web Settings part.

Consider a document in which the web setting allowPNG is applied. As a web setting this element specifies if the PNG graphics format will be used for persisting images when saving the document as a web page. Specifically, if the PNG graphics format will be used when saving a document as a web page, this requirement would be specified by adding the following WordprocessingML to the settings part:

```
<w:webSettings>
  <w:allowPNG />
</w:webSettings>
```

If this element is omitted, then the JPEG graphics format will be used for persisting images when saving the document as a web page.

2.17 Fields and Hyperlinks

2.17.1 Fields

Most text in a word processing document is static; that is, unless it is directly changed as the result of editing, its contents remain the same, no matter how the rest of the document might change. However, certain useful pieces of information can change value over the life of a document. Consider the case of a reference to a page number, as in "For more information on this topic, see page 56." Clearly, hard coding the page number as 56 means that that number will need to be manually replaced as the document's size or layout is changed. Even a simple change to any margin, line spacing, or font size can invalid such references.

Fields provide a mechanism for placeholders, such as page reference numbers, that can be added to a document such that those placeholders are replaced by their corresponding values when the document is rendered for display or print. Other applications for fields include, but are not limited to, automatic numbering of tables and figures, document creation and current date and time, document author information, and the computation of totals for a table column.

A *field* is a set of codes that instructs a WordprocessingML consumer to insert text, graphics, page numbers, and other material into a document automatically. (The DATE field causes the current date to be inserted.) The text or graphics inserted into a document when a consumer carries out a field's codes is referred to as the *field result* for that field. The act of carrying out a field's codes is referred to as a *field update*. As to how or when any field is updated is outside the scope of this standard.

2.17.2 Hyperlinks

As well as allowing for dynamic run content using fields, a WordprocessingML document may contain one or more *hyperlinks*, which allow for the linking of two disparate regions of WordprocessingML content (analogous to hyperlinks in HTML pages). WordprocessingML hyperlinks can be any of the following:

- Intradocument: A hyperlink can target any bookmark contained within the current WordprocessingML document.
- Interdocument: A hyperlink can target another WordprocessingML package, as well as specify a bookmark within that package.
- Other destinations: A hyperlink can target any other valid URI location.

2.18 Miscellaneous Topics

2.18.1 Text Boxes

All VML-based drawing objects (except for connectors) support the addition of rich WordprocessingML content within their extents. When WordprocessingML contents have been added to a VML drawing object, the resulting text is contained within a *text box*.

When WordprocessingML content is contained within a text box, it is represented within the object by specifying the VML textbox element, which contains within it a single txbxContent element that contains all of the desired WordprocessingML content. Text box content cannot contain references to other document stories, nor can it contain other txbxContent elements. That is, nested shapes cannot have rich content.

2.18.2 Subdocuments

Within a WordprocessingML document, it is sometimes necessary to break a large document into two or more separate WordprocessingML document files, allowing each of these files to be distributed, edited, and handled independently.

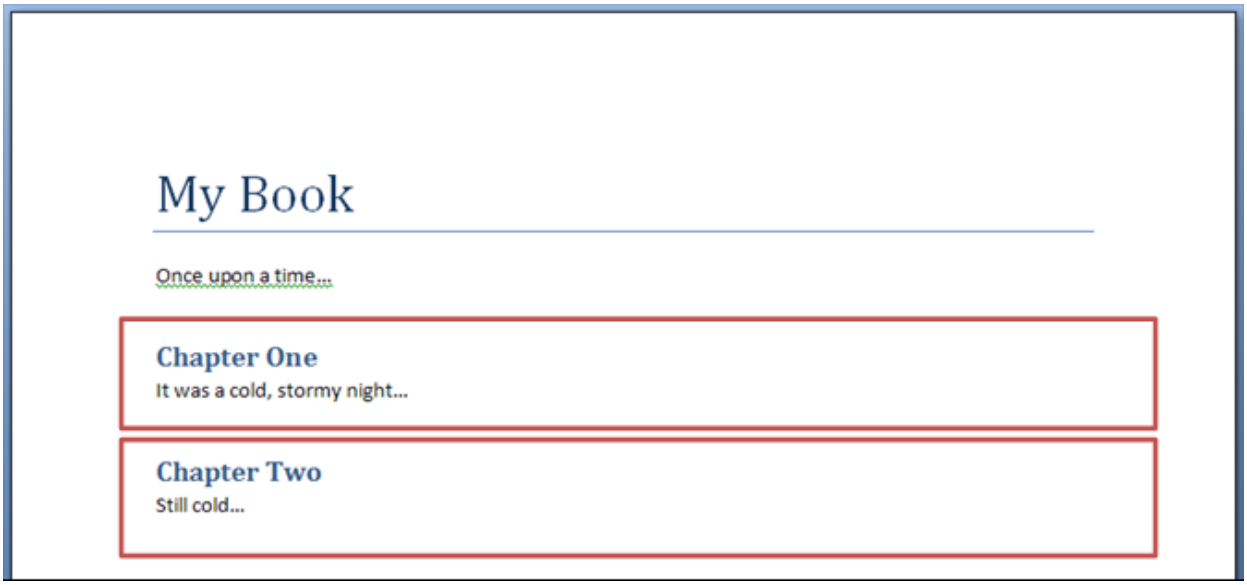
A book might consist of five chapters, each edited by a separate author. The editor for the book would therefore desire to create six WordprocessingML documents - one for each author to work on their chapter, and a main document which collates the content of the five chapters appropriately.

When a WordprocessingML document is composed of other WordprocessingML documents in this way, the resulting documents are a master document and its subdocuments.

- A *master document* is a document which incorporates one or more subdocuments (as well as optional WordprocessingML content) to create a larger document
- A *subdocument* is a WordprocessingML document—there is no specific information in a document which classifies it as such

Consider a WordprocessingML document, which is being used to write a book:

To allow this document to be written by multiple authors, each chapter in the book is placed in a separate file (the sections highlighted in red below):



The result is three WordprocessingML documents:

- A master document (containing the title of the book, the first paragraph, and references to the subdocuments for each chapter)
- Two subdocuments (one for each chapter)

2.18.3 Importing External Content

When generating WordprocessingML documents, it is sometimes necessary to include existing document content (henceforth called *external content*) within the document. External content in a document is typically

included because it was stored in a format other than the WordprocessingML format defined by this Office Open XML specification.

In order to facilitate the inclusion of such content without requiring its conversion as a prerequisite to its inclusion in a document, WordprocessingML includes the facility for applications to implement the import of external content in any format as part of a WordprocessingML document. This functionality, called *external content import*, allows the inclusion of content of an arbitrary content type within the WordprocessingML package, which can then be opened and merged into the main document when the package is consumed by applications which understand that content type.

Consider a WordprocessingML document which is being created based on the following existing HTML content:

```
<html … >
  <body style="margin-left:200px;margin-top:50px">
    <p>Paragraph one.</p>
    <blockquote style="border:5px solid #00FFFF">Paragraph in a
blockquote.</blockquote>
    <p>Paragraph two.</p>
  </body>
</html>
```

This content can be converted to its WordprocessingML equivalents using the XML syntax defined by this Office Open XML specification, or a more basic tool can use the external content import to include the HTML document within a WordprocessingML package, allowing a subsequent consumer of that content to import the resulting HTML. When the resulting WordprocessingML package is opened, the HTML document it could be read (if it is an alternate format understood by the consuming application) and migrated into the appropriate location in the main WordprocessingML document.

2.18.4 Roundtripping Alternate Content

Office Open XML defines a mechanism for the storage of content which is not defined by this Office Open XML specification, for example extensions developed by future software applications which leverage the Open XML formats. This mechanism allows for the storage of a series of alternative representations of content, of which the consuming application may use the first alternative whose requirements are met.

Consider an application which creates a new paragraph property intended to make the colors of its text change randomly when it is displayed. This functionality is not defined in this Office Open XML specification, and so the application might choose to create an alternative representation setting a different manual color on each character for clients which do not understand this extension using an AlternateContent block as follows:

```
<ve:AlternateContent xmlns:ve="…">
  <ve:Choice Requires="colors" xmlns:colors="urn:randomTextColors">
    <w:p>
      <w:pPr>
        <colors:random colors:val="true" />
      </w:pPr>
      <w:r>
        <w:t>Random colors!</w:t>
      </w:r>
    </w:p>
  </ve:Choice>
  <ve:Fallback>
    <w:p>
      <w:r>
        <w:rPr>
          <w:color w:val="FF0000" />
        </w:rPr>
        <w:t>R</w:t>
      </w:r>
      <w:r>
        <w:rPr>
          <w:color w:val="00FF00" />
        </w:rPr>
        <w:t>a</w:t>
      </w:r>
      </w:r>
      …
    </w:p>
  </ve:Fallback>
</ve:AlternateContent>
```

The Choice element that requires the new color extensions uses the random element in its namespace, and the Fallback element allows clients that do not support this namespace to see an appropriate alternative representation.

These alternate content blocks may occur at any location within a WordprocessingML document, and applications shall handle and process them appropriately (taking the appropriate choice).

However, WordprocessingML does not explicitly define a set of locations where applications shall attempt to store and roundtrip all non-taken choices whenever possible.

If an application does not understand the colors extension, the resulting file (if alternate choices are to be preserved would appear as follows:

```
<ve:AlternateContent xmlns:ve="…">
  <ve:Choice Requires="colors" xmlns:colors="urn:randomTextColors">
    …
  </ve:Choice>
  <ve:Fallback>
    …
  </ve:Fallback>
</ve:AlternateContent>
```

The file would then appear as follows after the choice is processed:

```
<w:p>
  <w:r>
    <w:rPr>
      <w:color w:val="FF0000" />
    </w:rPr>
    <w:t>R</w:t>
  </w:r>
  <w:r>
    <w:rPr>
      <w:color w:val="00FF00" />
    </w:rPr>
    <w:t>a</w:t>
  </w:r>
  …
</w:p>
```

End of informative text.

3. Introduction to SpreadsheetML

This clause is informative.

This clause contains a detailed introduction to the structure of a SpreadsheetML document.

3.1 Workbook

3.1.1 Overview

A *workbook* is composed of book-level properties and a collection of one or more *sheet*s. The sheets are the central working surface for a spreadsheet application. The workbook part and corresponding properties comprise data used to set application- and workbook-level operational state. The workbook also serves to bind all the sheets and child objects into an organized single file. The workbook properties include information about what application last saved the file, where and how the windows of the workbook were positioned, and an enumeration of the worksheets in the workbook.

3.1.2 Minimum Workbook Scenario

For the sake of simplicity, it is important to minimize the required set of workbook properties that must be present to compose a valid workbook. The smallest possible (blank) workbook must contain the following:

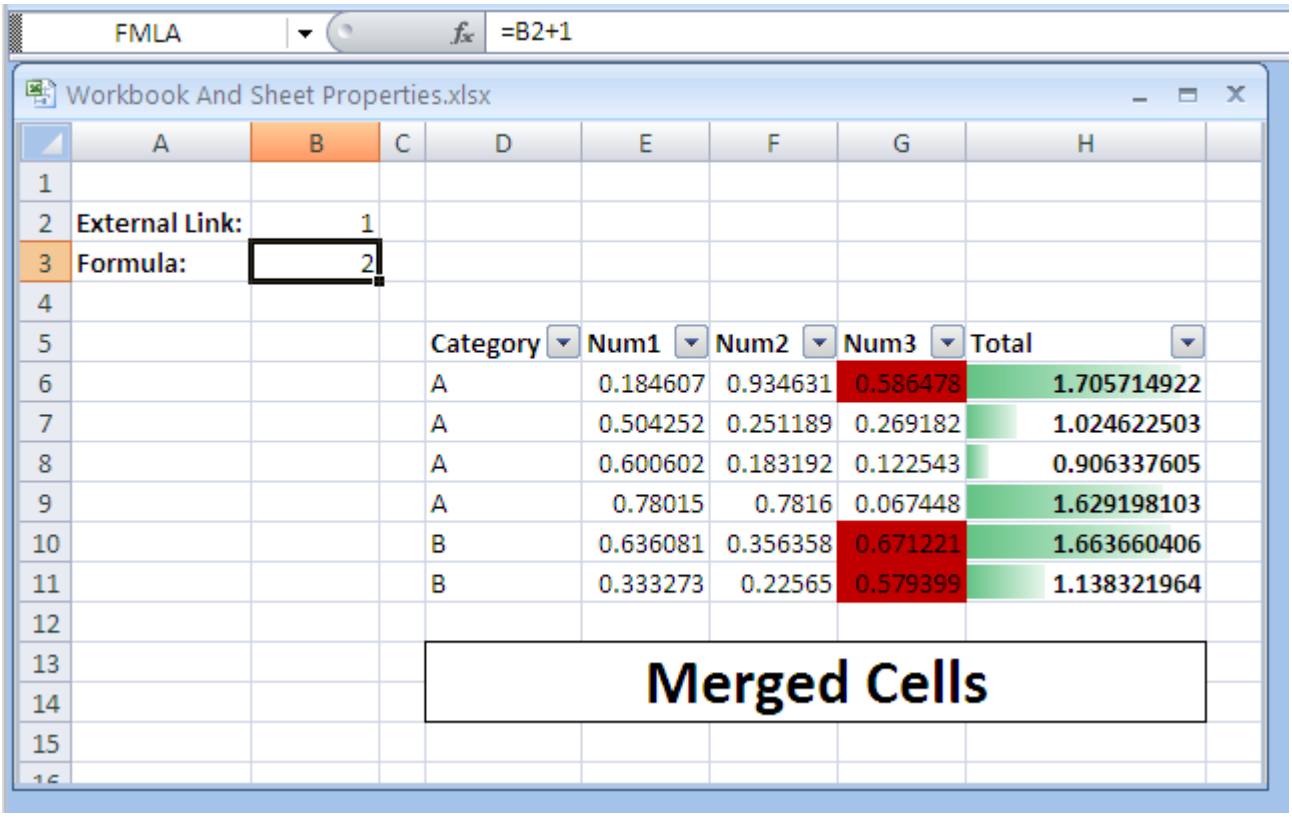
- A single sheet
- A sheet ID
- A relationship Id that points to the location of the sheet definition

For example:

```
<workbook>
  <sheets>
    <sheet name="Sheet1" sheetId="1" r:id="rId1"/>
  </sheets>
</workbook>
```

3.1.3 Example Workbook Properties

Consider the following graphical representation of a workbook:



The above example will have the following workbook properties definition:

```
<workbook>
  <fileVersion lastEdited="4" lowestEdited="4" rupBuild="3814"/>
  <workbookPr backupFile="1" saveExternalLinkValues="0" updateLinks="never"/>
  <calcPr calcId="122211" calcMode="manual" iterate="1"/>
  <bookViews>
    <workbookView showHorizontalScroll="0" showVerticalScroll="0"
      showSheetTabs="0" xWindow="45" yWindow="15" windowWidth="9420"
      windowHeight="5460" tabRatio="701"/>
  </bookViews>
  <sheets>
    <sheet name="Sheet1" sheetId="1" sh:id="rId1"/>
    <sheet name="Sheet2" sheetId="2" sh:id="rId2"/>
    <sheet name="Sheet3" sheetId="3" sh:id="rId3"/>
  </sheets>
</workbook>
```

The elements and attributes used here are discussed in more detail in the following subclauses.

3.1.4 fileVersion

This contains file versioning properties, as follows.

- lastEdited – The version of the application that last saved the file.
- lowestEdited – The earliest version of the application that saved the file. This value is reset any time an application that understands all data in the file saves the file.
- rupBuild – An incremental public release of the application (e.g., RTM version or SP1 version).
- workbookPr – A group of various workbook properties.
- backupFile – A flag that indicates whether the application should create a backup of the file in question during a save operation.
- saveExternalLinkValues – A flag that indicates whether the application should cache values retrieved from other workbooks via an externally linking formula during save. If `yes`, a supporting part is written out containing a cached cell table from the external workbook.
- updateLinks – A flag that dictates how external links are handled upon opening the file. In this example, `never` means don't ask the user if they want to refresh the cached values from an external workbook, and in fact, don't ever do it until the user initiates the action.
- calcPr – Various calculation properties grouped together.
- calcId – The version of the calculation engine used to calculate values in the workbook. When a newer version of the application opens a file with an older calcId value, the application performs a full calculation of all formulas immediately after opening the workbook, to ensure proper calculation results.
- calcMode – A flag that indicates when the application should calculate formulas:
  - `Manual` means to wait for the user to initate the action.
  - `Automatic` means to perform only the needed calculations whenever a cell value changes.
- Iterate – When formula references are circular (i.e., they refer back on themselves for required input), the `iterate` flag specifies that this is an intended and valid state. Further properties not discussed here control the number of iterative calculations to perform before stopping calculation.
- bookViews – A collection of views.

3.1.5 workbookView

A single view definition represented using the following flags:

- showHorizontalScroll – Controls visibility of the horizontal scroll bar of the application. In the example above, it is set to not being visible.
- showVerticalScroll – Controls visibility of the vertical scroll bar of the application. In the example above, it is set to not being visible.
- showSheetTabs – Controls visibility of the worksheet tabs in the application. In the example above, they are set to not being visible.
- xWindow – Specifies the x coordinate (in twips) of the upper right corner of the workbook window.
- yWindow – Specifies the y coordinate (in twips) of the upper right corner of the workbook window.

- windowWidth – Specifies the width of the workbook window.
- windowHeight – Specifies the height of the workbook window.
- tabRatio – Specifies the ratio between the workbook tabs bar and the horizontal scroll bar.
- Sheets – A collection of worksheets in the workbook.
- Sheet – A single sheet definition (book-level).
- Name – The name of the worksheet. These must be unique within the workbook.
- sheetId – The internal Id of the sheet. These must be unique within the workbook.
- Id - The relationship Id that points to the sheet part definition.

3.2 Sheets

*Sheet*s are the central structures within a workbook, and are where a user does most of his spreadsheet work. The most common type of sheet is the *worksheet*, which is represented as a grid of cells. Worksheet cells can contain text, numbers, dates, and formulas. Cells can also be formatted. A workbook usually contains more than one sheet. To aid in the analysis of data and the making of informed decisions, spreadsheet applications often implement features and objects which help calculate, sort, filter, organize, and graphically display information. Since these features are often connected very tightly with the spreadsheet grid, these are also included in the sheet definition on disk.

Other types of sheets include *chart sheet*s and *dialog sheet*s.

3.2.1 Minimum Worksheet Scenario

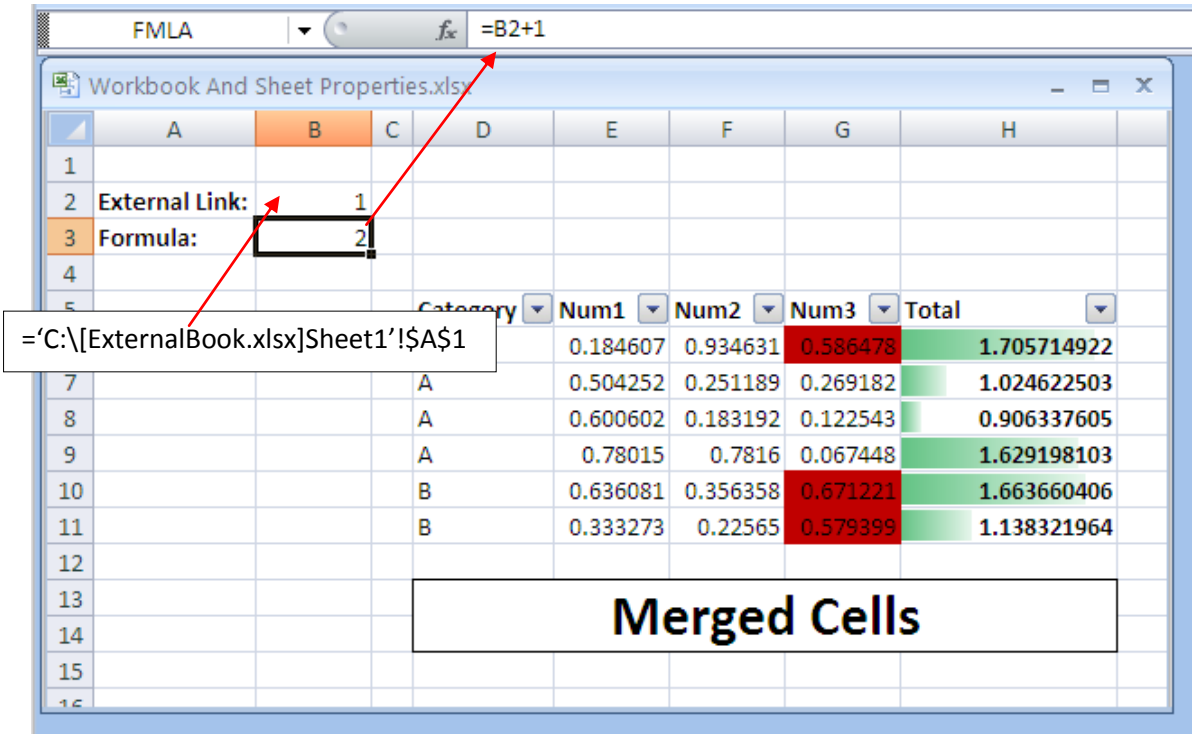
The smallest possible (blank) sheet is as follows:

```
<worksheet>
  <sheetData/>
</worksheet>
```

The empty sheetData collection represents an empty grid; this element is required. As defined in the schema, some optional sheet property collections can appear before sheetData, and some can appear after. To simplify the logic required to insert a new sheetData collection into an existing (but empty) sheet, the sheetData collection is required, even when empty.

3.2.2 Example Sheet

Consider the following graphical representation of a worksheet:



Notice that cells A2 and A3 contain text. Cell B1 contains a formula linking to another workbook, whose value is 1. Cell B2 contains a formula as well; this formula appears in the formula bar (top of picture) because it is the active cell. Cells D5:H5 contain bold-faced text that serves as headers for the table of data residing in D6:H11. The table of data has a filter feature applied to it (evidenced by drop down arrows in the header row), and columns G and H have different types of conditional formatting applied. Finally, cells D13:H14 are part of a merged cell feature, where a series of cells behave together as a single, larger cell.

When saved, the above example will have the syntax below written out in the corresponding sheet part. Sheet information is organized into three main sections:

1. Top-level sheet properties (everything before sheetData)
2. The cell table (sheetData)
3. Supporting sheet features (everything after sheetData)

Therefore, the XML for the above example would look like this, broken into three sections:

3.2.3 Sheet Properties

```
<worksheet>
  <sheetPr filterMode="1"/>
  <dimension ref="A2:H14"/>
```

```
    <sheetViews>
      <sheetView tabSelected="1" workbookViewId="0">
        <selection activeCell="B3" sqref="B3"/>
      </sheetView>
    </sheetViews>
    <sheetFormatPr defaultRowHeight="15"/>
    <cols>
      <col min="1" max="1" width="12.85546875" bestFit="1" customWidth="1"/>
      <col min="3" max="3" width="3.28515625" customWidth="1"/>
      <col min="4" max="4" width="11.140625" bestFit="1" customWidth="1"/>
      <col min="8" max="8" width="17.140625" style="1" customWidth="1"/>
    </cols>
```

3.2.4 Sheet Data

sheetData, which represents the cell table, directly after the cols collection:

```
  <sheetData>
    <row r="2" spans="1:2" customFormat="1">
      <c r="A2" s="1" t="s">
        <v>0</v>
      </c>
      <c r="B2">
        <f>[1]Sheet1!$A$1</f>
        <v>1</v>
      </c>
    </row>
    <row r="3" spans="1:8" customFormat="1">
      <c r="A3" s="1" t="s">
        <v>1</v>
      </c>
      <c r="B3">
        <f>B2+1</f>
        <v>2</v>
      </c>
      <c r="H3" s="1"/>
    </row>
    <row r="4" spans="1:8">
      <c r="H4"/>
    </row>
    <row r="5" spans="4:8">
      <c r="D5" s="1" t="s">
        <v>4</v>
      </c>
```

```
        <c r="E5" s="1" t="s">
          <v>5</v>
        </c>
        <c r="F5" s="1" t="s">
          <v>6</v>
        </c>
        <c r="G5" s="1" t="s">
          <v>7</v>
        </c>
        <c r="H5" s="1" t="s">
          <v>8</v>
        </c>
      </row>
      <row r="6" spans="4:8">
        <c r="D6" t="s">
          <v>2</v>
        </c>
        <c r="E6">

        <c r="G11">
          <v>0.5793989116090501</v>
        </c>
        <c r="H11" s="1">
          <f t="shared" ce="1" si="0">SUM(E11:G11)</f>
          <v>1.1383219636496344</v>
        </c>
      </row>
```

```
      <row r="13" spans="4:8">
        <c r="D13" s="2" t="s">
          <v>9</v>
        </c>
        <c r="E13" s="3"/>
        <c r="F13" s="3"/>
        <c r="G13" s="3"/>
        <c r="H13" s="4"/>
      </row>
      <row r="14" spans="4:8">
        <c r="D14" s="5"/>
        <c r="E14" s="6"/>
        <c r="F14" s="6"/>
        <c r="G14" s="6"/>
        <c r="H14" s="7"/>
      </row>
    </sheetData>
```

3.2.5 Supporting Features

The supporting feature definitions follow the cell table data:

```
    <sheetProtection objects="0" scenarios="0"/>
    <autoFilter ref="D5:H11">
      <filterColumn colId="0">
        <filters>
          <filter val="A"/>
        </filters>
      </filterColumn>
      <filterColumn colId="1">
        <customFilters and="1">
          <customFilter operator="greaterThan" val="0"/>
          <customFilter operator="lessThan" val="0.7"/>
        </customFilters>
      </filterColumn>
    </autoFilter>
    <mergeCells>
      <mergeCell ref="D13:H14"/>
    </mergeCells>
    <conditionalFormatting sqref="H6:H11">
      <cfRule type="dataBar" priority="3" stopIfTrue="0">
        <formula>MAX(IF(ISBLANK(H6:H11), "", IF(ISERROR(H6:H11), "",
          H6:H11)))</formula>
        <formula>MIN(IF(ISBLANK(H6:H11), "", IF(ISERROR(H6:H11), "",
          H6:H11)))</formula>
```

```
        <dataBar minLength="10" maxLength="90" showValue="1">
          <cfvo type="min" val="0"/>
          <cfvo type="max" val="0"/>
          <color rgb="FF63C384"/>
        </dataBar>
      </cfRule>
    </conditionalFormatting>
    <conditionalFormatting sqref="G6:G11">
      <cfRule type="cellIs" dxfId="0" priority="1" stopIfTrue="0"
        operator="greaterThan">
        <formula>0.5</formula>
      </cfRule>
    </conditionalFormatting>
    <printOptions/>
    <pageMargins left="0.7" right="0.7" top="0.75" bottom="0.75"
      header="0.3" footer="0.3"/>
    <pageSetup orientation="portrait" horizontalDpi="300" verticalDpi="300"/>
    <headerFooter/>
```

These elements are discussed in more detail in the following subclauses.

3.2.6 Sheet Properties

Referring back to §3.2.3, note that several sheet-level properties are expressed before the sheetData cell table is encountered.

sheetPr indicates that an AutoFilter has been applied on this sheet. Dimension indicates the used range on this sheet. There should be no data or formulas outside this range. The sheetViews collection indicates which cell is active on the sheet, and indicates whether this particular sheet is the active sheet in the workbook.

A collection of column-level settings appears in the cols collection.

Finally, within sheetFormatPr, a default row height is set.

3.2.7 sheetData Cell Table

The cell table is the core structure of a worksheet. It consists of all the text, numbers, and formulas in the grid.

3.2.8 Row

```
    <row r="2" spans="1:2" customFormat="1">
      <c r="A2" s="1" t="s">
        <v>0</v>
      </c>
```

```
    <c r="B2">
      <f>[1]Sheet1!$A$1</f>
      <v>1</v>
    </c>
  </row>
```

The cells in the cell table are organized by row. Each row has an index (attribute `r`) so that empty rows need not be written out. Each row indicates the number of cells defined for it, as well as their relative position in the sheet. In this example, the first row of data is row 2.

3.2.9 Cell

```
  <c r="B3">
    <f>B2+1</f>
    <v>2</v>
  </c>
```

The cell itself is expressed by the `c` collection. Each cell indicates it's location in the grid using A1-style reference notation. A cell can also indicate a style identifier (attribute `s`) and a data type (attribute `t`). The cell types include string, number, and Boolean. In order to optimize load/save operations, default data values are not written out.

3.2.9.1 Cell Values

Cells contain values, whether the values were directly typed in (e.g., cell A2 in our example has the value `External Link:`) or are the result of a calculation (e.g., cell B3 in our example has the formula `B2+1`).

String values in a cell are not stored in the cell table unless they are the result of a calculation. Therefore, instead of seeing `External Link:` as the content of the cell's `v` node, instead you see a zero-based index into the shared string table where that string is stored uniquely. This is done to optimize load/save performance and to reduce duplication of information. To determine whether the `0` in `v` is a number or an index to a string, the cell's data type must be examined. When the data type indicates string, then it is an index and not a numeric value.

3.2.9.2 Formulas

Cells can contain formulas, which calculate results. Formulas are expressed in the file the same way the user sees them at runtime of the application. This is specifically a design choice meant to aid in creation and processing of workbook contents.

A formula can have attributes on it indicating how to handle calculation of the cell.

3.2.9.2.1 Shared Formulas

```
<row r="7" spans="4:8">
  <c r="H7" s="1">
    <f t="shared" ref="H7:H11" ce="1" si="0">SUM(E7:G7)</f>
    <v>1.0246225028914113</v>
  </c>
</row>
<row r="8" spans="4:8">
  <c r="H8" s="1">
    <f t="shared" ce="1" si="0">SUM(E8:G8)</f>
    <v>0.9063376048733931</v>
  </c>
</row>
```

Just as strings in cells can be extremely pervasive and redundant in a sheet (and therefore must be optimized), formulas are also extremely pervasive in a sheet, and often can be optimized. Consider the table in the above example, where column H contains a formula that sums the numbers in columns E through G, for each row. The only difference between the formulas in H6:H12 is that the reference increases by 1 row from one row to the next. Therefore, an optimization is created where only the formula in H6 needs to be written out, with some additional information indicating how far to propagate the formula once loaded. This enables the loading application to load and parse only the first of the shared formulas, and then more quickly apply the necessary transforms to produce the additional related formulas in subsequent cells.

Note that while formulas can be shared, it is desirable to enable easy access to the contents of a cell. Therefore, it is allowed that all formulas may be written out, but only the primary formula in a shared formula need be loaded and parsed.

3.2.9.2.2 External Referencing Formulas

```
<c r="B2">
  <f>[1]Sheet1!$A$1</f>
  <v>1</v>
</c>
```

In the above example, cell B2 contains a formula that references a cell in another workbook, namely `'C:\[ExternalBook.xlsx]Sheet1'!$A$1`. This formula is referencing `ExternalBook.xlsx` located at `c:\`. Furthermore, the formula is requesting the value of cell A1 on `Sheet1` of that particular workbook.

Instead of writing `'C:\[ExternalBook.xlsx]Sheet1'!$A$1` directly in the formula, it is desirable to make all external references much more accessible, especially given the potentially enormous size of a cell table. Therefore, the URL and file location is persisted using the relationships semantic, in a relationship file, and then referenced inline with the formula: `[1]Sheet1!$A$1`. In this way, external resource files can more easily be determined and updated if needed.

Note that whenever a workbook contains a formula referencing another workbook, some values from that external workbook are also cached with the referencing workbook. This is done so that if a recalculation of the workbook is needed and the workbook isn't accessible, a cached value may be used to complete the calculation.

3.2.10 Supporting Sheet Features

3.2.11 Defined Names

```
<definedNames>
  <definedName name="FMLA">Sheet1!$B$3</definedName>
  <definedName name="SheetLevelName" comment="This name is scoped to Sheet1"
    localSheetId="0">Sheet1!$B$3</definedName>
</definedNames>
```

Defined names can be used in place of cell references in formulas. For example, instead of using B3+1 to add 1 to the value that's in B3, one could define a name, as in FMLA, and assign it to B3. Then FMLA+1 can be used to perform the calculation.

Names can be defined and assigned to a cell location or range or to a formula or constant value. Names can be referenced in formulas. Names can be scoped to either the entire workbook (default) or just the local sheet. Names scoped to the local sheet cannot be referenced from other sheets. Names scoped to the workbook can be referenced from any sheet.

Defined names are actually stored in the workbook part, but are discussed here in the context of the sheet because they are so closely related to cells and formulas.

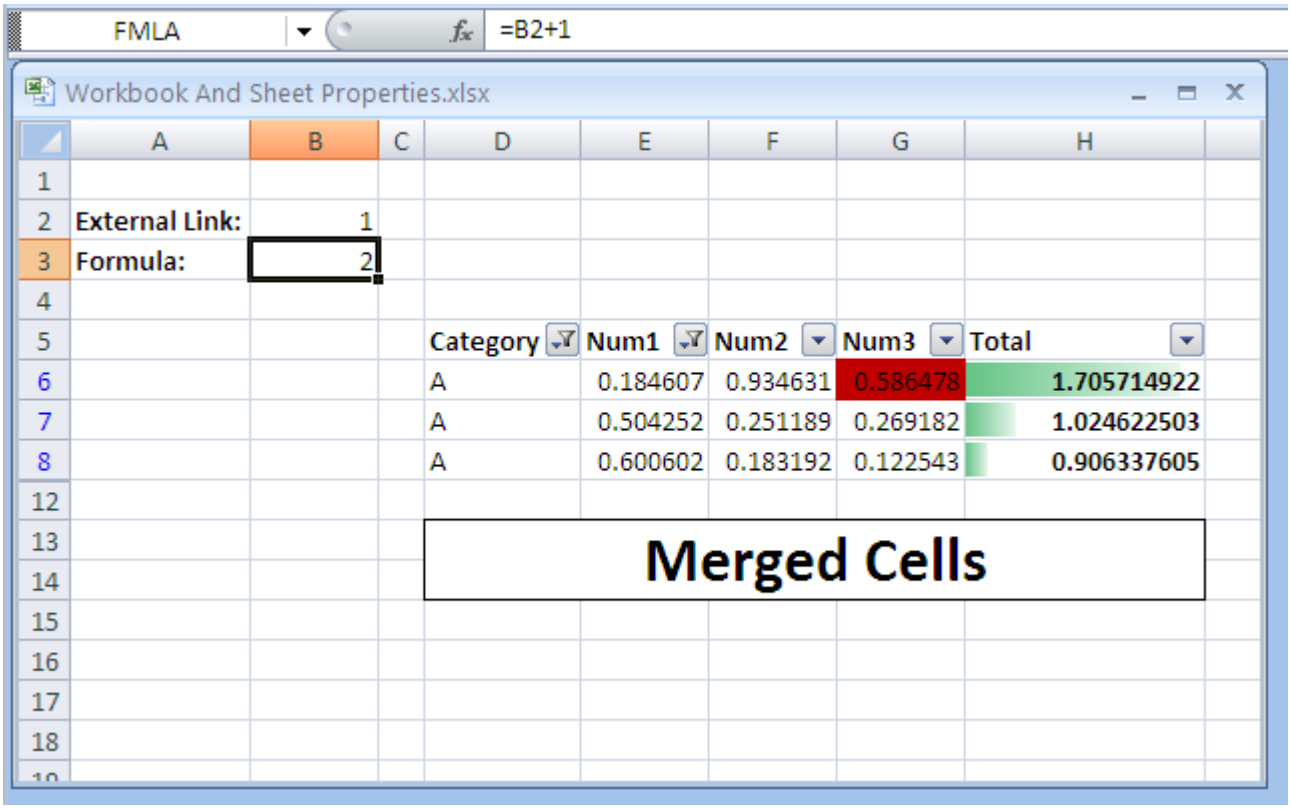
3.2.12 AutoFilter

```
<autoFilter ref="D5:H11">
  <filterColumn colId="0">
    <filters>
      <filter val="A"/>
    </filters>
  </filterColumn>
  <filterColumn colId="1">
    <customFilters and="1">
      <customFilter operator="greaterThan" val="0"/>
      <customFilter operator="lessThan" val="0.7"/>
    </customFilters>
  </filterColumn>
</autoFilter>
```

AutoFilters specify criteria for which cells in a table should be displayed. In this example, the first column (zero-based index colId) in the table (cells D5:D11), has a criteria specifying that only rows in the table whose value in column D are equal to A will be shown. The rest of the rows are *hidden*.

A second criterion is specified as well, on the 2nd column, E: only rows whose values in column E are greater than 0 and less than 0.7.

The resulting grid could be rendered like this:



3.2.13 Merged Cells

```
<mergeCells>
  <mergeCell ref="D13:H14"/>
</mergeCells>
```

In the example, cells D13:H14 have been merged into a single, larger cell. Note that the cell table itself doesn't reflect this merge, but it does reflect the data content and formatting. Specifically, the top-left cell in a merged collection of cells contains the value, and all the cells reflect the various border formatting.

3.2.14 Conditional Formatting

```
<conditionalFormatting sqref="H6:H11">
  <cfRule type="dataBar" priority="3" stopIfTrue="0">
    <formula>MAX(IF(ISBLANK(H6:H11), "", IF(ISERROR(H6:H11), "",
      H6:H11)))</formula>
    <formula>MIN(IF(ISBLANK(H6:H11), "", IF(ISERROR(H6:H11), "",
      H6:H11)))</formula>
```

```
      <dataBar minLength="10" maxLength="90" showValue="1">
        <cfvo type="min" val="0"/>
        <cfvo type="max" val="0"/>
        <color rgb="FF63C384"/>
      </dataBar>
    </cfRule>
  </conditionalFormatting>
  <conditionalFormatting sqref="G6:G11">
    <cfRule type="cellIs" dxfId="0" priority="1" stopIfTrue="0"
  operator="greaterThan">
      <formula>0.5</formula>
    </cfRule>
  </conditionalFormatting>
```

There are two conditional formats applied: one to the table of data in column H and the other to the table of data in column G.

In column G, a red fill is applied to any cell whose value is greater than 0.5. Notice that sqref specifies the range to which the rule applies. The formatting is specified by dxfId, which is a reference to a formatting expression in the central styles part.

In column H there is a dataBar formatting rule, which applies a variable length bar to the cell background, where the length of the bar depends on the relative value of the cell.

3.3 Shared String Table

3.3.1 Overview

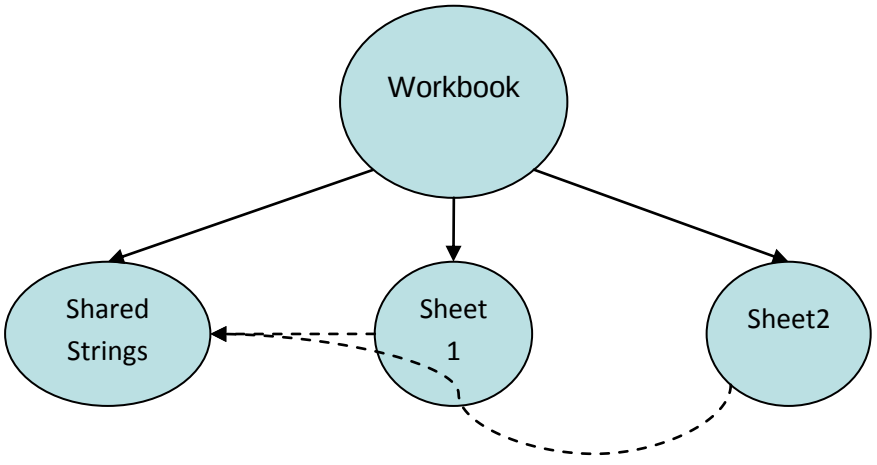
A workbook may contain thousands of cells containing string (non-numeric) data. Furthermore, this data is very likely to be repeated across many rows or columns. The goal of implementing a single string table that is shared across the workbook is to improve performance in opening and saving the file by only reading and writing the repetitive information once.

For example, consider a workbook summarizing information for cities within various countries. There may be a column for the name of the country, a column for the name of each city in that country, and a column containing the data for each city:

	A	B	C	D
1				
2		**Country**	**City**	**Data**
3		United States	Seattle	469.83
4		United States	Denver	36.16
5		United States	New York	114.38
6		United States	Philadelphia	540.95
7		United States	Houton	649.07
8		United States	San Diego	258.4
9		United States	San Francisco	686.05
10		Argentina	Buenos Aires	14.08
11		Argentina	San Juan	28.17
12		Argentina	Salta	757.31
13		Argentina	Rosario	246.23
14		Argentina	La Plata	947.63
15		Japan	Tokyo	597.55
16		Japan	Nagoya	619.01
17		Japan	Yokohama	525.14
18		Japan	Sendai	611.74
19				

In this case, the country name is repetitive, being duplicated in many cells. In many cases, the repetition is extensive, and a tremendous savings is realized by making use of a shared string table when saving the workbook.

3.3.2 File Architecture



There is a single shared strings part for all the strings in a workbook. This part is related to the workbook. Each cell (in sheet1.xml, for example) containing a string value refers by index to a string expressed in the shared

strings part. The solid arrows represent relationships among the parts and the dotted arrows represent references by index to a string in the shared strings part.

3.3.3 Example: Plain Text

This first example demonstrates plain text in cells. Note that in this example, some of the cells are formatted (e.g., the column headers "Country", "City", and "Data" are bold faced). Since the formatting is applied at the cell level, cell styles and formatting is used to describe the formatting, rather than using text formatting on the text itself.

A later example demonstrates how to handle a variety of text formatting (rich text) within a single cell.

3.3.4 Illustration

Consider the example in the introduction:

	A	B	C	D
1				
2		**Country**	**City**	**Data**
3		United States	Seattle	469.83
4		United States	Denver	36.16
5		United States	New York	114.38
6		United States	Philadelphia	540.95
7		United States	Houton	649.07
8		United States	San Diego	258.4
9		United States	San Francisco	686.05
10		Argentina	Buenos Aires	14.08
11		Argentina	San Juan	28.17
12		Argentina	Salta	757.31
13		Argentina	Rosario	246.23
14		Argentina	La Plata	947.63
15		Japan	Tokyo	597.55
16		Japan	Nagoya	619.01
17		Japan	Yokohama	525.14
18		Japan	Sendai	611.74
19				

In this example, the country names in the column titled 'Country'—"United States", "Argentina", and "Japan"—would appear a single time in the shared strings part. Additionally, all the city names (in the column titled 'City') would appear a single time in the shared strings part, as would the column titles themselves in B2:D2. The numeric values in the 'Data' column would be expressed inline with the cell table definition (e.g., in Sheet1.xml).

3.3.5 The XML

The shared string table XML for this example looks like this:

```
<sst … count="35" uniqueCount="22">
  <si>
    <t>United States</t>
  </si>
  <si>
    <t>Seattle</t>
  </si>
  <si>
    <t>Denver</t>
  </si>
  <si>
    <t>New York</t>
  </si>
  <si>
    <t>Philadelphia</t>
  </si>
  <si>
   <t>Houton</t>
  </si>
  <si>
    <t>San Diego</t>
  </si>
  <si>
    <t>San Francisco</t>
  </si>
  <si>
    <t>Argentina</t>
  </si>
  <si>
    <t>Buenos Aires</t>
  </si>
  <si>
   <t>San Juan</t>
  </si>
  <si>
    <t>Salta</t>
  </si>
  <si>
    <t>Rosario</t>
  </si>
  <si>
    <t>La Plata</t>
  </si>
```

```
    <si>
      <t>Japan</t>
    </si>
    <si>
      <t>Tokyo</t>
    </si>
    <si>
      <t>Nagoya</t>
    </si>
    <si>
      <t>Yokohama</t>
    </si>
    <si>
      <t>Sendai</t>
    </si>
    <si>
      <t>Country</t>
    </si>
    <si>
      <t>City</t>
    </si>
    <si>
      <t>Data</t>
    </si>
  </sst>
```

The cell table for this example looks like this:

```
  <sheetData>
    <row r="2" spans="2:4" customFormat="1">
      <c r="B2" s="1" t="s">
        <v>19</v>
      </c>
      <c r="C2" s="1" t="s">
        <v>20</v>
      </c>
      <c r="D2" s="1" t="s">
        <v>21</v>
      </c>
    </row>
    <row r="3" spans="2:4" customFormat="1">
      <c r="B3" t="s">
        <v>0</v>
      </c>
```

```
        <c r="C3" t="s">
          <v>1</v>
        </c>
        <c r="D3">
          <f t="shared" ref="D3:D18" ca="1" si="0">ROUND(RAND()*1000,2)</f>
          <v>374.9</v>
        </c>
      </row>
      <row r="4" spans="2:4" customFormat="1">
        <c r="B4" t="s">
          <v>0</v>
        </c>
        <c r="C4" t="s">
          <v>2</v>
        </c>
        <c r="D4">
          <f t="shared" ca="1" si="0"/>
          <v>452.82</v>
        </c>
      </row>
      <row r="5" spans="2:4" customFormat="1">
        <c r="B5" t="s">
          <v>0</v>
        </c>
        <c r="C5" t="s">
          <v>3</v>
        </c>
        <c r="D5">
          <f t="shared" ca="1" si="0"/>
          <v>632.1</v>
        </c>
      </row>
      <row r="6" spans="2:4" customFormat="1">
        <c r="B6" t="s">
          <v>0</v>
        </c>
        <c r="C6" t="s">
          <v>4</v>
        </c>
        <c r="D6">
          <f t="shared" ca="1" si="0"/>
          <v>374.9</v>
        </c>
      </row>
      <row r="7" spans="2:4" customFormat="1">
        <c r="B7" t="s">
          <v>0</v>
        </c>
        <c r="C7" t="s">
          <v>5</v>
        </c>
        <c r="D7">
          <f t="shared" ca="1" si="0"/>
          <v>452.82</v>
        </c>
      </row>
      <row r="8" spans="2:4" customFormat="1">
        <c r="B8" t="s">
          <v>0</v>
        </c>
        <c r="C8" t="s">
          <v>6</v>
        </c>
        <c r="D8">
          <f t="shared" ca="1" si="0"/>
          <v>632.1</v>
        </c>
      </row>
      <row r="9" spans="2:4" customFormat="1">
        <c r="B9" t="s">
          <v>7</v>
        </c>
        <c r="C9" t="s">
          <v>1</v>
        </c>
        <c r="D9">
          <f t="shared" ca="1" si="0"/>
          <v>374.9</v>
        </c>
      </row>
      <row r="10" spans="2:4" customFormat="1">
        <c r="B10" t="s">
          <v>7</v>
        </c>
        <c r="C10" t="s">
          <v>2</v>
        </c>
        <c r="D10">
          <f t="shared" ca="1" si="0"/>
          <v>452.82</v>
        </c>
      </row>
      <row r="11" spans="2:4" customFormat="1">
        <c r="B11" t="s">
          <v>7</v>
        </c>
        <c r="C11" t="s">
          <v>3</v>
        </c>
        <c r="D11">
          <f t="shared" ca="1" si="0"/>
          <v>632.1</v>
        </c>
      </row>
      <row r="12" spans="2:4" customFormat="1">
        <c r="B12" t="s">
          <v>7</v>
        </c>
        <c r="C12" t="s">
          <v>4</v>
        </c>
        <c r="D12">
          <f t="shared" ca="1" si="0"/>
          <v>374.9</v>
        </c>
      </row>
      <row r="13" spans="2:4" customFormat="1">
        <c r="B13" t="s">
          <v>7</v>
        </c>
        <c r="C13" t="s">
          <v>5</v>
        </c>
        <c r="D13">
          <f t="shared" ca="1" si="0"/>
          <v>452.82</v>
        </c>
      </row>
      <row r="14" spans="2:4" customFormat="1">
        <c r="B14" t="s">
          <v>7</v>
        </c>
        <c r="C14" t="s">
          <v>6</v>

      <c r="C18" t="s">
        <v>18</v>
      </c>
      <c r="D18">
        <f t="shared" ca="1" si="0"/>
        <v>979.22</v>
      </c>
    </row>
  </sheetData>
```

3.3.6 Shared String Table

```
  <sst … count="35" uniqueCount="22">
    <si>
      <t>United States</t>
    </si>
    <si>
      <t>Seattle</t>
    </si>
    <si>
      <t>Denver</t>
    </si>
```

Examining the XML for the shared string part, it can be found that the first entry in the string table is "United States", residing in position 0. The value "Seattle" can be found in position 1 and "Denver" can be found in position 2.

3.3.7 Cell Table

```
<row r="2" spans="2:4" customFormat="1">
  <c r="B2" s="1" t="s">
    <v>19</v>
  </c>
  <c r="C2" s="1" t="s">
    <v>20</v>
  </c>
  <c r="D2" s="1" t="s">
    <v>21</v>
  </c>
</row>
```

The first cell in our spreadsheet that contains data is B2. The XML indicates that it is of type 'string' (`t="s"`). This indicates that the numeric value found inside the `<v>` element is an index to a string in the string table rather than an actual number in the spreadsheet. The value for cell B2 is '19'. The 19th entry in the shared string table (counting the first entry as 0) has a value of "Country". Therefore, cell B2 contains the word "Country".

```
<row r="3" spans="2:4" customFormat="1">
  <c r="B3" t="s">
    <v>0</v>
  </c>
  <c r="C3" t="s">
    <v>1</v>
  </c>
  <c r="D3">
    <f t="shared" ref="D3:D18" ca="1" si="0">ROUND(RAND()*1000,2)</f>
    <v>374.9</v>
  </c>
</row>
```

Cell B3 (`<c @r="B3"…>`) is also of type string, and the '0' inside the `v` element refers to the 0th item in the string table, which corresponds to the string value "United States". Cell C3 is a string type of cell and references the shared string found in position 1 in the string table, corresponding to the value "Seattle". Cell D3 contains an `f` element, indicating a formula.

```
<row r="4" spans="2:4" customFormat="1">
  <c r="B4" t="s">
    <v>0</v>
  </c>
  <c r="C4" t="s">
    <v>2</v>
  </c>
```

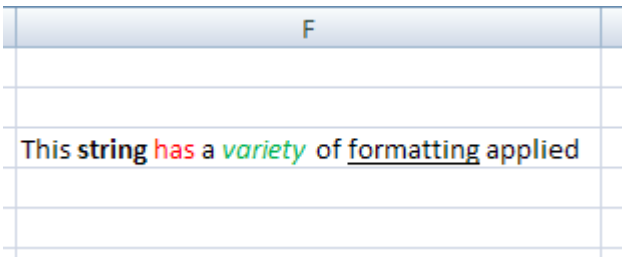
```
    <c r="D4">
      <f t="shared" ca="1" si="0"/>
      <v>452.82</v>
    </c>
  </row>
```

Examining the cell table entries for the data in row 4 of the spreadsheet, we see that cell B4 also contains the string value "United States". This is the 2nd occurrence of the value "United States" in this example. Since this value only occurs once in the string table, again the cell is using an index of 0 to reference the string item in the string table. Cell C4 is of type string and an index value of '2' indicates that "Denver" is the value of this cell.

3.3.8 Example: Rich Text

In this example, a single string cell value has multiple types of text formatting applied to various parts of the text.

3.3.9 Illustration



3.3.10 Shared String Table

The main difference between plain text and rich text is seen in the string table itself. The si element is capable of containing rich text expressions:

```
  <si>
    <r>
      <t xml:space="preserve">This </t>
    </r>
    <r>
      <rPr>
        <b/>
        <sz val="11"/>
        <color theme="1"/>
        <rFont val="Calibri"/>
        <family val="2"/>
        <scheme val="minor"/>
      </rPr>
      <t xml:space="preserve">string </t>
    </r>
```

```
      <r>
        <rPr>
          <sz val="11"/>
          <color rgb="FFFF0000"/>
          <rFont val="Calibri"/>
          <family val="2"/>
          <scheme val="minor"/>
        </rPr>
        <t>has</t>
      </r>
      <r>
        <rPr>
          <sz val="11"/>
          <color theme="1"/>
          <rFont val="Calibri"/>
          <family val="2"/>
          <scheme val="minor"/>
        </rPr>
        <t xml:space="preserve"> a </t>
      </r>
      <r>
        <rPr>
          <i/>
          <sz val="11"/>
          <color rgb="FF00B050"/>
          <rFont val="Calibri"/>
          <family val="2"/>
          <scheme val="minor"/>
        </rPr>
        <t>variety</t>
      </r>
      <r>
        <rPr>
          <sz val="11"/>
          <color theme="1"/>
          <rFont val="Calibri"/>
          <family val="2"/>
          <scheme val="minor"/>
        </rPr>
        <t xml:space="preserve"> of </t>
      </r>
      <r>
```

```
        <rPr>
          <u/>
          <sz val="11"/>
          <color theme="1"/>
          <rFont val="Calibri"/>
          <family val="2"/>
          <scheme val="minor"/>
        </rPr>
        <t>formatting</t>
      </r>
      <r>
        <rPr>
          <sz val="11"/>
          <color theme="1"/>
          <rFont val="Calibri"/>
          <family val="2"/>
          <scheme val="minor"/>
        </rPr>
        <t xml:space="preserve"> applied</t>
      </r>
    </si>
```

Reading the string from left to right as it appears in the cell, each word represents a change in formatting. This change in formatting corresponds to separate run elements r to separate the text with different formatting. Every word is expressed using a run element r, which expresses the properties of the text rPr and the text itself t.

Since there are no properties associated with the first word "This", the text inherits the default formatting for the cell.

The rich text expression for the second string "string" contains a bold faced font element indicator b in the run properties rPr, therefore this text will have bold face applied. While other text formatting properties are expressed, they are the same as the cell formatting. This additional information is expressed for the sake of clarity and completeness of expression.

The rich text expression for the third string "has" contains a color element indicator color in the run properties rPr. Therefore, the color of the text associated with this set of run properties will be red, according to the color value expressed.

The formatting for the remaining words in this rich text string can be deduced in a similar manner, such that "a" has default formatting applied, "variety" is both italicized and green, "of" has default formatting applied, "formatting" is underlined, and "applied" has default formatting applied.

3.4 Tables

3.4.1 Overview

A table helps organize and provide structure to lists of information in a worksheet. Tables have clearly labeled columns, rows, and data regions. Tables enable users to sort, analyze, format, manage, add, and delete information. Here's an example of what a table can look like:

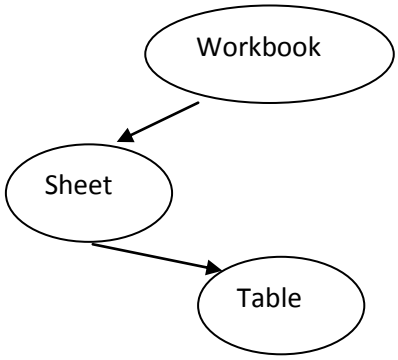
	A	B	C	D
1				
2		State	City	Zipcode
3		WA	Seattle	98101
4		WA	Seattle	98102
5		WA	Tacoma	98467
6		OR	Portland	97204
7		OR	Portland	97205
8		ID	Post Falls	83854
9		Count		6

Notice that this table has column headings "State", "City", and "Zipcode". There is a row summarizing the data, in this case a count of zip codes. The formatting helps make clear where the column headings are (Bold faced, bordered on top and bottom all the way across), where the data region is (banded row stripes), and where the totals row is (double border separating data from totals, bold face totals label).

Because the table feature has been applied to this data, special behaviors can be applied which help the user perform useful actions. For example, if the user types additional data in row 10, the table can expand and automatically add that data to the data region of the table. Similarly, adding a column is as easy as typing a new column heading to the right or left of the current column headings. Filter and sort abilities are automatically surfaced to the user via the drop down arrows. Special calculated columns can be created which summarize or calculate data in the table. These columns have the ability to expand and shrink according to size of the table, and maintain proper formula referencing.

Tables can be made from data already present in the worksheet. Tables can also be the result of an external data query. Finally, tables can be the result of mapping a collection of repeating XML elements to a worksheet range.

3.4.2 File Architecture



Each table is referred to by a relationship from a sheet to the table. The relationship is found in the sheet's _rels directory. The sheet XML also references the ID of this relationship, because there can be more than one table in a sheet.

The sheet XML stores the numeric and textual data. The table XML records the various attributes for the particular table object.

3.4.3 Example: Table

This example demonstrates a table created from data that was previously entered in the sheet. (See §3.15 for a discussion of Tables with XML data bindings.)

3.4.4 Illustration

Consider the example provided in §3.4.1 above:

	A	B	C	D
1				
2				
3		State	City	Zipcode
4		WA	Seattle	98101
5		WA	Seattle	98102
6		WA	Tacoma	98467
7		OR	Portland	97204
8		OR	Portland	97205
9		ID	Post Falls	83854
10		**Count**		6
11				

Notice that this table has column headings "State", "City", and "Zipcode". There is a row summarizing the data, in this case a count of Zip codes. In the "State" column abbreviations of United States State names are listed. In the City column are listed names of Cities within those states. Finally, within the Zipcode column are postal codes residing within those cities.

The table has a style applied, which provides unique formatting for:

- The column heading area, with bold facing and top and bottom borders
- The data area, with banded striping
- The total row area, with a top double border and bold facing
- The last column area, with a solid background fill of blue.

3.4.5 The Sheet XML

The sheet XML for this example references the table definition part:

```
      …
      <tableParts count="1">
        <tablePart r:id="rId1"/>
      </tableParts>
  </worksheet>
```

3.4.6 The Table XML

The tableParts collection appears after the sheetData section of the sheet. This sheet references a table whose relationship Id r:id value is `rId1`.

The Table definition XML for this example:

```
  <table xmlns= … id="8" name="Table19" displayName="Table19" ref="B3:D10"
    totalsRowCount="1">
    <autoFilter ref="B3:D10"/>
    <tableColumns count="3">
      <tableColumn id="1" name="State" totalsRowLabel="Count"
        totalsRowDxfId="0"/>
      <tableColumn id="2" name="City"/>
      <tableColumn id="3" name="Zipcode" totalsRowFunction="count"/>
    </tableColumns>
    <tableStyleInfo name="TableStyleMedium16" showFirstColumn="0"
      showLastColumn="1"
      showRowStripes="1" showColumnStripes="0"/>
  </table>
```

name indicates that the Table's name is `Table19`, and the ref value indicates that it occupies the range `B3:D10` on the relevant sheet. totalsRowCount value of `1` indicates that this Table's total row is visible.

The autoFilter element indicates that the autoFilter feature is applied to the range `B3:D10`. The tableColumns collection indicates there are 3 columns in the table, whose names are "State", "City", and "Zipcode". Furthermore, the column titled "State" has a label in the total row, whose caption is "Count", and the column titled "Zipcode" has a total row function applied, whose function is "count".

The tableStyleInfo element indicates various attributes of this Table's style and formatting. In this example, name indicates that the Table style named "TableStyleMedium16" has been applied. Additionally, even though formatting has been defined by this table style to indicate uniquely the first column of the table, since showFirstColumn is set to `0` (false), this first column formatting will not be applied to the table. The same is true for column stripes. Since showColumnStripes is set to `0` (false), even though formatting for column stripes is defined by the table style, it is not applied to this table. However, both row striping and last column formatting is set to be applied to this table, as indicated by showRowStripes and showLastColumn.

3.5 Calculation Chain

3.5.1 Overview

The Calculation Chain part specifies the order in which cells in the workbook were last calculated. It only records information about cells containing formulas. It does *not* include any information about the formula-dependency calculation tree. In other words, the Calculation Chain part does not indicate the dependencies that formulas have on other cell values; it only indicates the order in which the cells were last calculated.

Any particular calculation event can cause the calculation chain order to be rearranged or altered. For example, adding more formulas to the workbook will add references in the Calculation Chain part.

Another example of how the calculation order can be updated involves the idea of partial calculation. *Partial calculation* is an optimization a spreadsheet application can implement to calculate only those cells that are dependent on other cells whose values have changed, and to ignore other formulas in the workbook. This helps to avoid redundantly recalculating results that are already known. Therefore, if a set of formulas that were previously ignored during a calculation become required for calculation (due to a cell's value changing), then these formulas will move to "first" on the calculation chain so they can be evaluated.

While calculation chain information can be loaded by a spreadsheet application, it is not required. A calculation chain can be constructed in memory at load-time based on the formulas and their interdependence, if the spreadsheet application finds this information useful. The order expressed in the Calculation Chain part does not force or dictate to the implementing application the order in which calculations must be performed at runtime.

3.5.2 Example

Consider the following set of formulas in a workbook:

	A		B		C		D	
1	1	1	11	11				
2	=A1+1	2	=B1+1	12				
3	=A2+1	3	=B2+1	13				
4	=A3+1	4	=B3+1	14				
5	=A4+1	5	=B4+1	15				
6	=A5+1	6	=B5+1	16				
7	=A6+1	7	=B6+1	17				
8	=A7+1	8	=B7+1	18				
9	=A8+1	9	=B8+1	19				
10	=A9+1	10	=B9+1	20	=B10+A10	30	=C10+10	40
11								

Note that the content of each cell is displayed on the left side of the cell, and the evaluated value is superimposed on the right side of each cell.

Cell A1 contains the numeric constant 1. Cell A2 contains the formula =A1+1, and this formula is filled down to A10. Cell B1 contains the numeric constant 11. Cell B2 contains the formula =B1+1, and this formula is filled down to B10. C10 contains the formula =B10+A10, whose current value is 30. D10 contains the formula =C10+10, whose current value is 40.

Because dependencies among formulas do affect calculation order, dependencies will be discussed briefly here. The formula in D10 depends on the result from C10. The formula in C10 depends on the results from both A10 and B10. The formulas in column A each depend on the cell above them, ultimately depending on the constant value in A1. The formulas in column B each depend on the cell above them, ultimately depending on the constant value in B1.

This example was created by first entering the values in A1 then B1. Next, typing the formula in A2, and filling that across to B2. Then the formulas in A2 and B2 were concurrently filled down to A10:B10. Next, the formula was typed into C10, and finally the formula in D10 was entered. The application was in automatic/partial calculation mode when this information was entered.

3.5.2.1 Partial Calculation

The calculation chain might be saved after initially entering the data and saving the workbook, as follows:

```
<calcChain xmlns="…">
  <c r="D10" i="1"/>
  <c r="C10"/>
  <c r="A3"/>
  <c r="B3"/>
  <c r="A4"/>
  <c r="B4"/>
  <c r="A5"/>
  <c r="B5"/>
  <c r="A6"/>
  <c r="B6"/>
  <c r="A7"/>
  <c r="B7"/>
  <c r="A8"/>
  <c r="B8"/>
  <c r="A9"/>
  <c r="B9"/>
  <c r="A10"/>
  <c r="B10"/>
  <c r="B2"/>
  <c r="A2"/>
</calcChain>
```

Every c element represents a cell containing a formula. The first cell calculated appears first (top-to-bottom), and so on. The reference attribute r indicates the cell's address in the sheet. The index attribute i indicates the

index of the sheet with which that cell is associated. The sub-chain attribute s (not present in this first example) indicates that this cell can be treated as a sub chain of the preceding cell. Sub-chains can be useful when calculation can be multi-threaded or calculated concurrently. Whenever a cell does not contain an i or s attribute, it is understood to inherit these values from the previous cell.

Because of the way in which the workbook was initially created and saved, cell D10 should be the first cell calculated. The reason for this, which cannot be determined from examining the XML, is that cell D10 is the only cell that needs calculating, due to the partial calculation optimization. Since the cells A2:B10 and C10 were previously calculated (as a result of entering formulas in those cells), when entering the formula in D10, D10 is the only cell that needs to be calculated.

This calculation chain indicates that after D10 is calculated, C10 can be evaluated. In looking at the dependencies, it is understood that during a full calculation, C10 would be evaluated before D10 can be evaluated. However, because of the partial calculation optimization, at the time C10 was entered, it was placed first on the calculation chain to be evaluated. Subsequent to that, D10 was entered, and so C10 was moved to second position in the calculation chain, and that is why it is currently in the second place.

Moving through the rest of the cells with this same logic, just before C10 was entered, A3, then B3, then A4, then B4, and so on up to A10 and B10 were added and then evaluated as part of the fill-down operation.

Finally, cells A2 and B2 were the first formulas to be added and calculated. All formulas in the workbook were added after A2 and B2 were evaluated. Since A2 and B2 didn't need to be re-evaluated (due to the partial calculation optimization) after that, they eventually settled to the end of the calculation chain.

3.5.2.2 First Full Calculation

Below is how the calculation chain will look after changing the values of A1 and B1, or after forcing the application to perform a full calculation on the entire set of formulas:

```
<calcChain xmlns="…">
  <c r="B2" i="1"/>
  <c r="B3" s="1"/>
  <c r="B4" s="1"/>
  <c r="B5" s="1"/>
  <c r="B6" s="1"/>
  <c r="B7" s="1"/>
  <c r="B8" s="1"/>
  <c r="B9" s="1"/>
  <c r="B10" s="1"/>
  <c r="C10" s="1"/>
  <c r="D10" s="1"/>
  <c r="A2"/>
  <c r="A3" s="1"/>
  <c r="A4" s="1"/>
```

```
    <c r="A5" s="1"/>
    <c r="A6" s="1"/>
    <c r="A7" s="1"/>
    <c r="A8" s="1"/>
    <c r="A9" s="1"/>
    <c r="A10" s="1"/>
  </calcChain>
```

Now the order of calculation seems more in line with the way in which the formulas depend on each other: cells B2:B10 are calculated in order, and cells A2:A10 are calculated in order.

Additionally, the application has discovered that the formulas in column B can be calculated in parallel with the formulas in column A (i.e., they don't depend on each other). This is evidenced by the presence of s="1" on the cell element for cells B2:B10, indicating that B2:10 are part of a "child-chain" starting with B2. Note also that C10 and B10 are included in that child chain, even though these formulas do, in fact, depend on calculated values from column A. This is due to the multi-threaded nature of the calculation engine. Currently the chain on which C10 and D10 reside can be calculated concurrently with the chain on which A2:A10 reside because by the time C10 and D10 need to be calculated (e.g., by CPU #1), A10 has already been calculated (e.g., by CPU #2). In some future calculation, the timing may be different, and at that time, the application will need to resort to moving C10 and D10 to a new calculation level (see §3.5.2.3).

3.5.2.3 Twentieth 20th Full Calculation

After several full calculation iterations, this particular calculation chain will settle into a stable state. For example:

```
  <calcChain xmlns="…">
    <c r="B2" i="1"/>
    <c r="B3" s="1"/>
    <c r="B4" s="1"/>
    <c r="B5" s="1"/>
    <c r="B6" s="1"/>
    <c r="B7" s="1"/>
    <c r="B8" s="1"/>
    <c r="B9" s="1"/>
    <c r="B10" s="1"/>
    <c r="A2"/>
    <c r="A3" s="1"/>
    <c r="A4" s="1"/>
    <c r="A5" s="1"/>
    <c r="A6" s="1"/>
```

```
      <c r="A7" s="1"/>
      <c r="A8" s="1"/>
      <c r="A9" s="1"/>
      <c r="A10" s="1"/>
      <c r="C10" l="1"/>
      <c r="D10" s="1"/>
    </calcChain>
```

The difference introduced here is the concept of a dependency-level attribute `l`. This flag indicates that all chain and child chain concurrent calculation must be completed (and all cells will have newly calculated values) before proceeding with calculation.

In this example, cells `C10` and `D10` are marked to exist in a new and separate dependency level from the cells `A2:A10` and `B2:B10`. This makes sense given how the dependencies for these formulas are set up: `A2:A10` can be calculated concurrently with `B2:B10` because they do not depend on each other. `A2:A10` exists as one calculation chain, and `B2:B10` exist as another parallel calculation chain. However, `C10` and `D10` are both dependent on calculated results from the two parallel chains, and so can only be calculated after the first set of parallel calculations are completed.

Dependency-Level `l` flags indicate where calculation must wait for all concurrent threads to complete before continuing with calculation

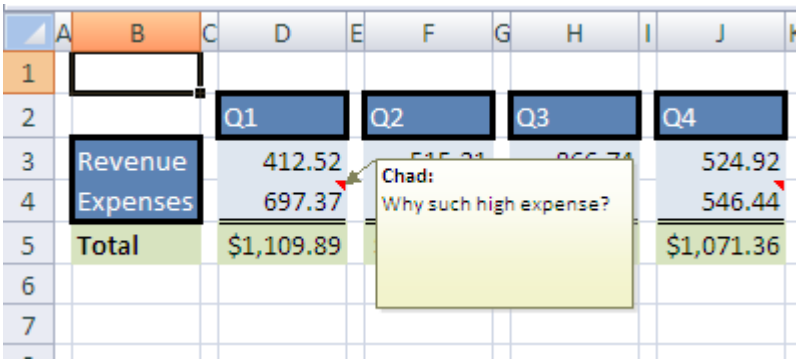
3.6 Comments

3.6.1 Overview

A *comment* is a rich text note that is attached to, and associated with, a cell, separate from other cell content. Comment content is stored separate from the cell, and is displayed in a drawing object (like a text box) that is separate from, but associated with, a cell. Comments are used as reminders, such as noting how a complex formula works, or to provide feedback to other users. Comments can also be used to explain assumptions made in a formula or to call out something special about the cell.

3.6.2 Example

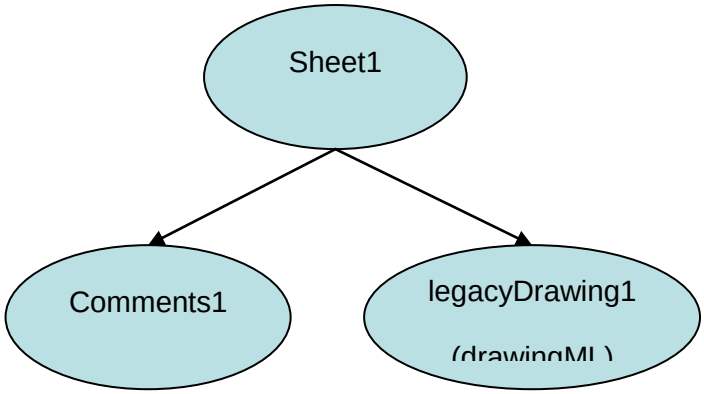
Consider the following graphic representation of a worksheet:



Note that cells D4 and J4 have comments.

3.6.3 File Architecture

Inside the file, the comment content ("Comments1") is expressed separately from the sheet information ("Sheet1"), and separately from the drawing information ("legacyDrawing1") for the containing object:



The parts are related using relationships from the sheet to the comments and drawings parts. Comments are stored together at the sheet-level. Therefore, if there are five worksheets in a workbook, and three of those contain cells with associated comments, there will be three comment parts in the file, one for each sheet.

3.6.4 The XML

```
<comments>
  <authors>
    <author>Chad</author>
    <author>CBR</author>
  </authors>
  <commentList>
    <comment ref="D4" authorId="0">
      <text>
        <r>
          <rPr>
            <b/>
            <sz val="8"/>
            <color indexed="81"/>
            <rFont val="Calibri"/>
            <charset val="1"/>
            <scheme val="minor"/>
          </rPr>
          <t>Chad:</t>
        </r>
```

```
            <r>
              <rPr>
                <sz val="8"/>
                <color indexed="81"/>
                <rFont val="Calibri"/>
                <charset val="1"/>
                <scheme val="minor"/>
              </rPr>
              <t xml:space="preserve">Why such high expense?</t>
            </r>
          </text>
        </comment>
        <comment ref="J4" authorId="1">
          <text>
            <r>
              <rPr>
                <b/>
                <sz val="8"/>
                <color indexed="81"/>
                <rFont val="Calibri"/>
                <charset val="1"/>
                <scheme val="minor"/>
              </rPr>
              <t>CBR:</t>
            </r>
            <r>
              <rPr>
                <sz val="8"/>
                <color indexed="81"/>
                <rFont val="Calibri"/>
                <charset val="1"/>
                <scheme val="minor"/>
              </rPr>
              <t xml:space="preserve">
                Pending a couple expenses in December.</t>
            </r>
          </text>
        </comment>
      </commentList>
    </comments>
```

3.6.5 Authors

```
<comments>
  <authors>
    <author>Chad</author>
    <author>CBR</author>
  </authors>
```

The authors collection is a unique list of author names for all comments on a particular sheet. In this example, there are two authors listed. Each comment definition references the authors collection by zero-based index.

3.6.6 Comments

```
<commentList>
  <comment ref="D4" authorId="0">
    <text>
      <r>
        <rPr>
          <b/>
          <sz val="8"/>
          <color indexed="81"/>
          <rFont val="Calibri"/>
          <charset val="1"/>
          <scheme val="minor"/>
        </rPr>
        <t>Chad:</t>
      </r>
      <r>
        <rPr>
          <sz val="8"/>
          <color indexed="81"/>
          <rFont val="Calibri"/>
          <charset val="1"/>
          <scheme val="minor"/>
        </rPr>
        <t xml:space="preserve">
          Why such high expense?</t>
      </r>
    </text>
  </comment>
```

commentList is a listing of all comments on a sheet. The first comment in this example has ref="D4" and authorId="0". This indicates that the comment is associated with cell D4 and is associated with the author "Chad".

The content of comment is rich text, following the rich text schematics, including the author name and actual comment.

3.7 Styles

3.7.1 Overview

There are several ways to express formatting applied to objects in a worksheet. SpreadsheetML supports the concepts of Styles, Themes, and Direct Formatting applied to cell ranges, Tables, PivotTables, Charts, and Shapes.

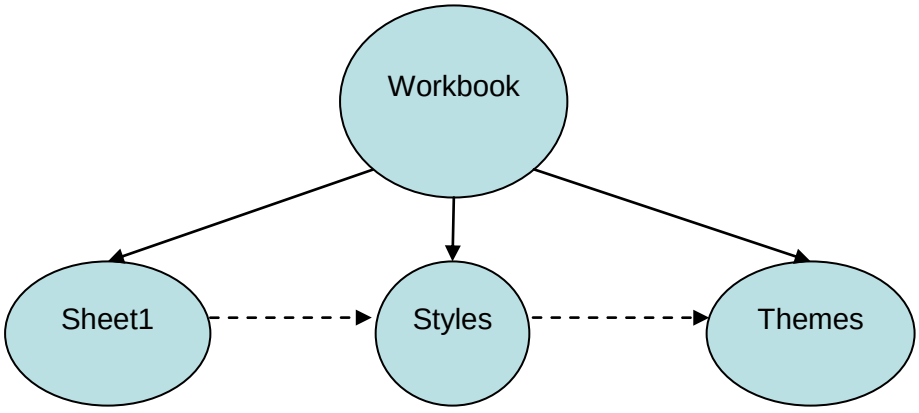
A *Style* is a named collection of formatting elements. A *cell style* can specify number format, cell alignment, font information, cell border specifications, colors, and background / foreground fills. *Table styles* specify formatting elements for the regions of a table (e.g. make the header row & totals bold face, and apply light gray fill to alternating rows in the data portion of the table to achieve striped or banded rows). *PivotTable styles* specify formatting elements for the regions of a PivotTable (e.g. 1st & 2nd level subtotals, row axis, column axis, and page fields).

A *Style* can specify color, fonts, and shape effects directly, or these elements can be referenced indirectly by referring to a *Theme* definition. Using *styles* allows for quicker application of formatting and more consistently stylized documents.

Themes define a set of colors, font information, and effects on shapes (including Charts). If a style or formatting element defines its color, font, or effect by referencing a theme, then picking a new theme switches all the colors, fonts, and effects for that formatting element.

Applying *Direct Formatting* means that particular elements of formatting (e.g. a bold font face or a number format) have been applied, but the elements of formatting have been chosen individually instead of collectively by choosing a named *Style*. Note that when applying direct formatting, themes can still be referenced, causing those elements to change as the theme is changed.

3.7.2 File Architecture



For a workbook, a single Styles part holds all its formatting definitions. Similarly, a single Themes part defines the theme information used in the workbook. These parts are referenced by relationship from the Workbook

part. Each of the formatted objects refers by index to a master formatting definition record expressed in the Styles part. This master formatting record references additional supporting formatting element collections in the Styles part. If the formatting element in the Styles part is defined in terms of a theme, then this formatting element will reference an index to a theme element defined in the Theme part. The solid arrows denote that there are relationships expressed from the Workbook part to each of the Sheet1, Styles, and Themes parts. The dotted arrow from the Sheet1 part to the Styles part indicates that there are references in the Sheet1 part's markup that refer, by index, to elements defined in the markup in the Styles part. Similarly, the dotted arrow from the Styles part to the Themes part indicates that there are references in the Styles part's markup that refer, by index, to elements defined in the markup in the Themes part.

3.7.3 Organization in the Styles Part

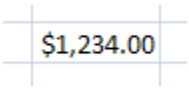
The Styles part is organized into element collections as described in the following subclauses. The element collections must appear in the order presented below. The element collections are siblings in the Styles part XML definition, whose parent, the root node of this part, is `<styleSheet>`.

Please refer to the reference material or schemas themselves for more precise descriptions on the required order of elements.

3.7.3.1 Number Format Expressions

This is where cell number formats used in this workbook are expressed. This collection never references a theme. In this collection the `numFmtId` attribute is an actual ID, unlike the other sibling collections. That is, instead of relying on the order in which a particular `numFmt` appears, it is referenced elsewhere by calling out the `numFmtId` value. Then the corresponding `numFmt` record can be found by finding the `numFmt` record with the matching `numFmtId` value. In the case of number formats, a set of `numFmtId` values are predefined and fixed by this specification. These values map to actual number formatting expressions.

The following XML would format a cell containing the value 1234 to look like this:



```
<numFmts count="1">
    <numFmt numFmtId="165" formatCode="&amp;quot;$&amp;quot;#,##0.00"/>
</numFmts>
```

A `<numFmt>` definition is referenced by ID (`numFmtId`) from either a `<cellXf>` or a `<cellStyleXf>`.

To read more about how to interpret number format codes like the value found in `formatCode` above, please read the reference section on `numFmt`, in the Styles section.

3.7.3.2 Font Definitions

This is where font definitions used in this workbook are expressed. Elements of the font definition may reference theme definitions.

```
<fonts count="1">
    <font>
          <b/>
          <sz val="11"/>
          <color theme="1"/>
          <name val="Calibri"/>
          <family val="2"/>
    </font>
</fonts>
```

This font definition specifies bold face, font size of "11", a font color specified in the Theme part, specifically the color whose index is "1" in the `<clrScheme>` collection, a font name of "Calibri", and whose font family value is "2" (for more explanation on font family, please refer to the Styles reference material). A `<font>` definition is referenced by index (`fontId`) from either a `<cellXf>` or a `<cellStyleXf>`.

A `font` record is referenced by zero-based index, meaning the numerical order in which the `font` appears under `fonts`.

3.7.3.3 Fill Definitions

This is where fills used in the workbook are expressed.

```
<fills count="1">
    <fill>
          <patternFill patternType="solid">
                <fgColor theme="4"/>
                <bgColor theme="4"/>
          </patternFill>
    </fill>
</fills>
```

This fill definition specifies a solid pattern fill, whose color uses a themed color, whose index is "4" in the `<clrScheme>` collection of the Theme part. A `<fill>` definition is referenced by index (`fillId`) from either a `<cellXf>` or a `<cellStyleXf>`.

A `fill` record is referenced by zero-based index, meaning the numerical order in which the `fill` appears under `fills`.

3.7.3.4 Borders Definitions

This is where border formats are specified.

```
<borders count="1">
    <border>
          <left/>
```

```
            <right/>
            <top/>
            <bottom/>
            <diagonal/>
        </border>
    </borders>
```

This example specifies a cell with left, right, top, and bottom borders. A `<border>` definition is referenced by index (`borderId`) from either a `<cellXf>` or a `<cellStyleXf>`.

A `border` record is referenced by zero-based index, meaning the numerical order in which the `border` appears under `borders`.

3.7.3.5 Master Records - Cell Styles

The 'master' cell style record (`<xf>`) ties together all the formatting (e.g. number format, font information, and fill) for a named cell style. An `<xf>` inside `<cellStyleXfs>` is referenced by zero-based index (not ID) (`xfId`) from a `<cellStyle>` definition, which names a particular cell style.

```
    <cellStyleXfs count="1">
        <xf numFmtId="0" fontId="0" fillId="0" borderId="0"/>
    </cellStyleXfs>
```

3.7.3.6 Master Records - Formatting

The 'master' cell style record (`<xf>`) ties together all the formatting (e.g. number format, font information, and fill) for a cell's direct formatting. An `<xf>` inside `<cellXfs>` is referenced by zero-based index (not ID) (`s`) from a cell definition (`<c>`) in one of the sheets.

```
    <cellXfs count="1">
        <xf numFmtId="0" fontId="0" fillId="0" borderId="0" xfId="0"/>
    </cellXfs>
```

3.7.3.7 Cell Styles

This is a collection of cell styles used in the workbook.

```
    <cellStyles count="1">
        <cellStyle name="Accent1" xfId="1" builtinId="29"/>
    </cellStyles>
```

3.7.3.8 Differential Formatting Records

"Differential formatting" enables subsets of formatting to be specified, without overriding other elements of formatting. For example, if it is desired to express "add bold face to whatever formatting is already there", then a `<dxf>` definition can be used. `<dxf>` definitions are used to express additional (or "differential") formatting that will be applied via Table styles or PivotTable styles. `<dxf>` definitions are referenced by index

(dxfId) from a <tableStyleElement>. The formatting elements used in a <dxf> definition are subsets of formatting collections described above.

A dxf record is referenced by zero-based index, meaning the numerical order in which the dxf appears under dxfs.

```
<dxfs count="1">
    <dxf>
          <font>
                <b/>
                <color theme="0"/>
          </font>
          <fill>
                <patternFill patternType="solid">
                      <fgColor theme="5"/>
                      <bgColor theme="5"/>
                </patternFill>
          </fill>
    </dxf>
</dxfs>
```

3.7.3.9 Custom Table Style Definitions

Built-in Table and PivotTable styles are not saved out, only custom-defined styles are saved out. In this example, a custom table style defines formatting for an element of a table, the "whole table" region.

```
<tableStyles count="1" defaultTableStyle="TableStyleMedium9"
defaultPivotStyle="PivotStyleLight16">
    <tableStyle name="TableStyleMedium10 - Custom" pivot="0" count="1">
          <tableStyleElement type="wholeTable" dxfId="6"/>
    </tableStyle>
</tableStyles>
```

3.7.4 Example

3.7.4.1 Illustration

For this example, consider this graphic representation of a worksheet:

		Q1	Q2	Q3	Q4
	Revenue	412.52	515.21	866.74	524.92
	Expenses	697.37	539.72	149.51	546.44
	Total	$1,109.89	$1,054.93	$1,016.25	$1,071.36

Column1	Column2	Column3	Column4
A	381.41	513.27	357.29
B	470.33	411.76	723.52
C	624.47	287.49	365.38
D	17.77	775.36	969.69

Column4	(All)

	Data	
Filter rows	Sum of Column2	Sum of Column3
A	381.41	513.27
B	470.33	411.76
C	624.47	287.49
D	17.77	775.36
Grand Total	1493.98	1987.88

Looking at the top left region of the illustration, cells D2, F2, H2, J2, and B3:B4 have the cell style "Accent1" applied to them. "Accent1" is a theme-driven style, and results in a blue cell fill and white / Calibri font formatting. Additionally these cells have direct border formatting applied which isn't specified as part of the "Accent1" cell style.

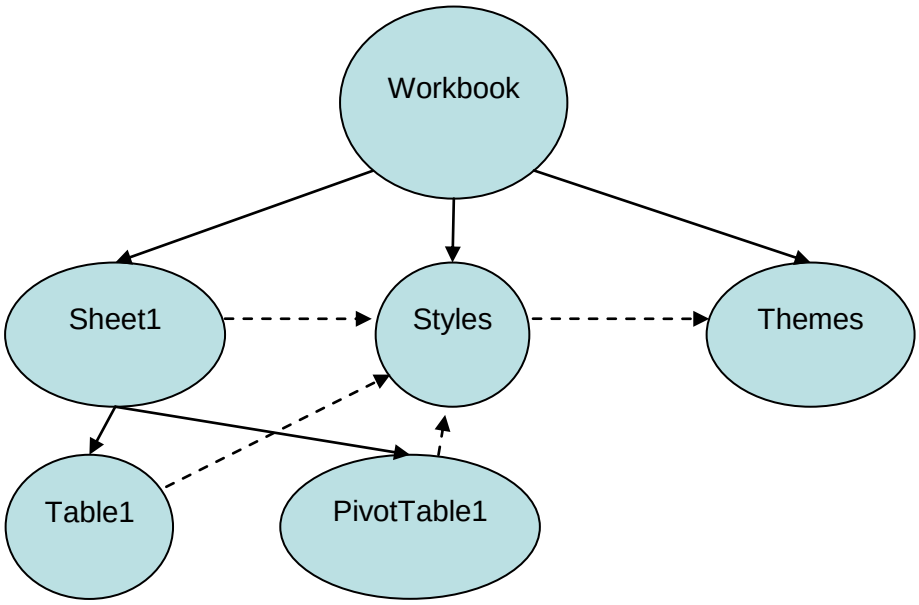
Cells D3:D4, F3:F4, H3:H4, and J3:J4 have a light blue cell fill applied. The light blue color is part of a themed color scheme, and will update when a new theme is selected.

Cells D5, F5, H5, and J5 have a currency number format applied as well as a green cell fill. While the cell fill is a themed color, the number format is fixed and will not vary or change if a new theme is selected.

The table in L2:O6 has a table style applied, called "TableStyleMedium10", which specifies formatting for the header row, row striping, and total row (even though the total row isn't shown in this example).

The PivotTable in L9:N17 has a PivotTable style applied, called "PivotStyleMedium10", which specifies formatting for the regions of a PivotTable, including the page field area in L9:M9, the header row area in L11:N12, the totals row in L17:N17, and the body of data in L13:N16.

3.7.4.2 File Architecture



All of the cells illustrated are defined in the "Sheet1" part in this example. The table is defined in the "Table1" part and the PivotTable is defined in the part named "PivotTable1". Each of the formatted objects refers to a set of formatting definitions which are expressed in the "Styles" part. If the formatting element is part of a themed set, the element will reference a theme element defined in the "Themes" part. The solid arrows represent relationships among the parts, the dotted arrows represent references by Id or index to various elements in the target part.

3.7.4.3 The XML For This Example

```
<styleSheet>
    <numFmts count="1">
          <numFmt numFmtId="164" formatCode="&quot;$&quot;#,##0.00"/>
    </numFmts>
    <fonts count="5">
          <font>
                <sz val="11"/>
                <color theme="1"/>
                <name val="Calibri"/>
                <scheme val="minor"/>
          </font>
          <font>
                <b/>
                <sz val="11"/>
                <color theme="1"/>
                <name val="Calibri"/>
                <family val="2"/>
          </font>
```

```
            <font>
                  <b/>
                  <sz val="8"/>
                  <color indexed="81"/>
                  <name val="Calibri"/>
                  <charset val="1"/>
                  <scheme val="minor"/>
            </font>
            <font>
                  <sz val="8"/>
                  <color indexed="81"/>
                  <name val="Calibri"/>
                  <charset val="1"/>
                  <scheme val="minor"/>
            </font>
            <font>
                  <sz val="11"/>
                  <color theme="0"/>
                  <name val="Calibri"/>

                        <bottom style="medium">
                              <color theme="1"/>
                        </bottom>
                  </border>
            </dxf>
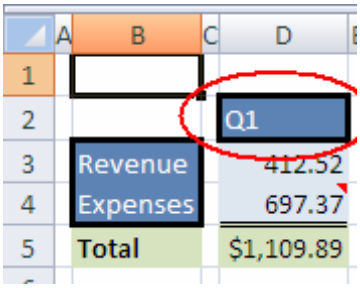
      </dxfs>
      <tableStyles count="1" defaultTableStyle="TableStyleMedium9"
   defaultPivotStyle="PivotStyleLight16">
            <tableStyle name="TableStyleMedium10 - Custom" pivot="0" count="7">
                  <tableStyleElement type="wholeTable" dxfId="6"/>
                  <tableStyleElement type="headerRow" dxfId="5"/>
                  <tableStyleElement type="totalRow" dxfId="4"/>
                  <tableStyleElement type="firstColumn" dxfId="3"/>
                  <tableStyleElement type="lastColumn" dxfId="2"/>
                  <tableStyleElement type="firstRowStripe" dxfId="1"/>
                  <tableStyleElement type="firstColumnStripe" dxfId="0"/>
            </tableStyle>
      </tableStyles>
      <colors/>
   </styleSheet>
```

3.7.4.4 Cell D2 Formatting



Cell D2 contains the text "Q1" and is defined in the cell table of sheet1 as:

```
   <c r="D2" s="7" t="s">
      <v>0</v>
   </c>
```

On this cell, the attribute value `s="7"` indicates that the 7th (zero-based) `<xf>` definition of `<cellXfs>` holds the formatting information for the cell. The 7th `<xf>` of `<cellXfs>` is defined as:

```
<xf numFmtId="0" fontId="4" fillId="2" borderId="2" xfId="1" applyBorder="1"/>
```

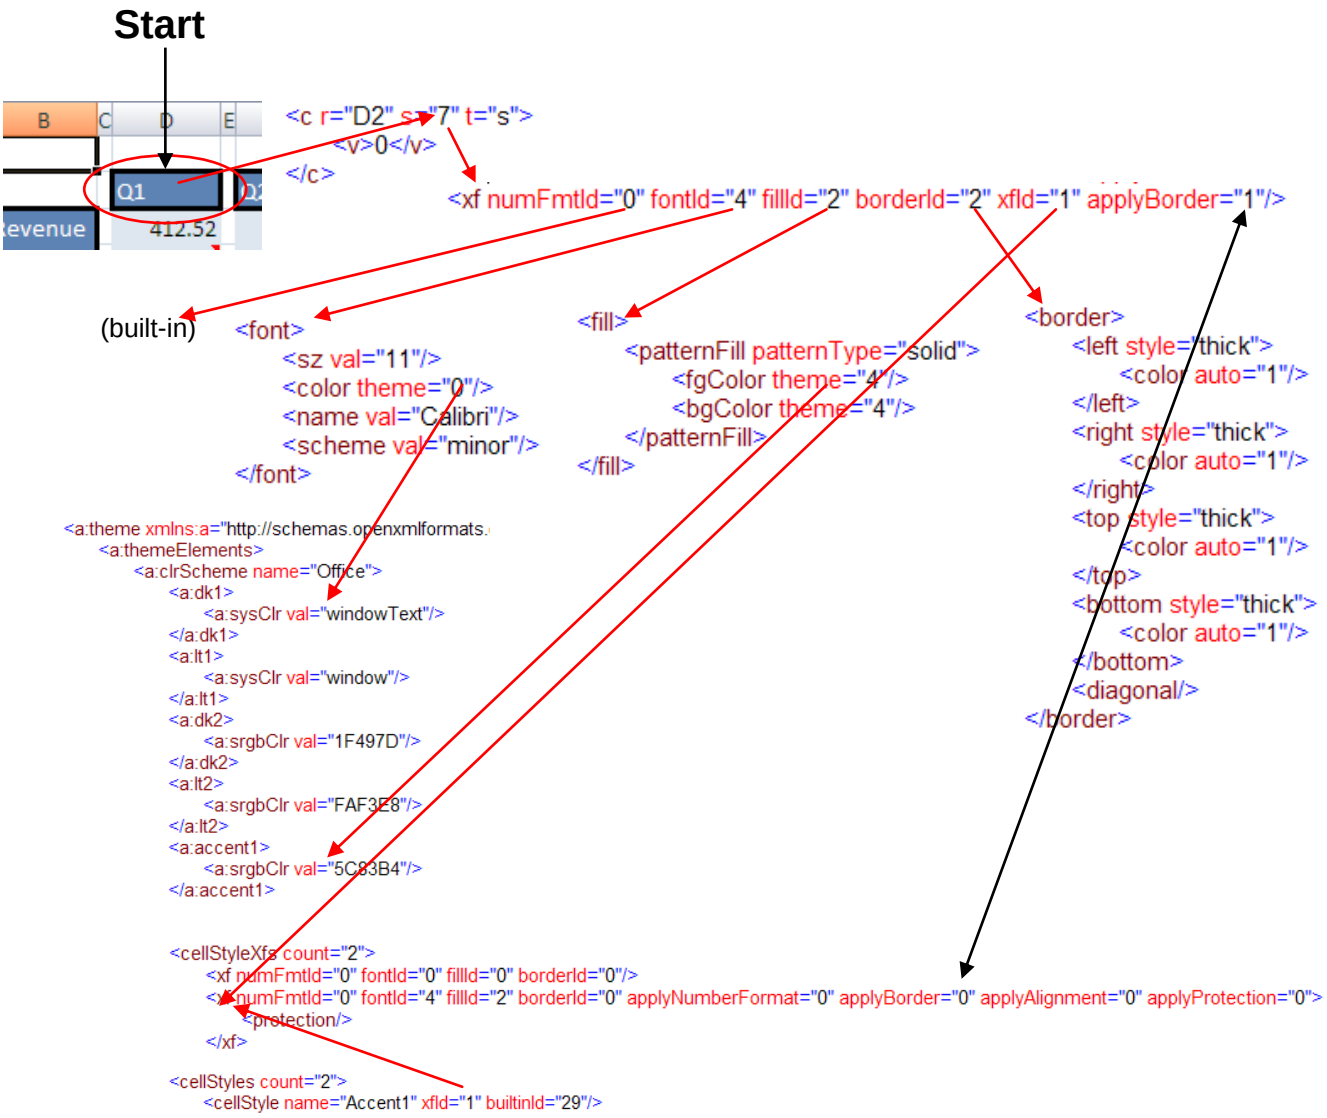
The number formatting information cannot be found in a `<numFmt>` definition because it is a built-in format; instead, it is implicitly understood to be the 0th built-in number format. Remembering that the indexes to other element collections are also zero-based, the font information can be found in the 4th `<font>` definition; the fill information in the 2nd `<fill>` definition; and the border information in the 2nd `<border>` definition. The cell uses a cell style which is defined in the 1st `<cellStyleXf>` definition and, finally, borders specified in this master formatting record should be applied.

Remember that these collections are zero-based.

Additionally the `<fill>` definition for D2 references a themed color, whose index is 4th in the `<clrScheme>` definition of the theme part:

```
<fill>
      <patternFill patternType="solid">
            <fgColor theme="4"/>
            <bgColor theme="4"/>
      </patternFill>
</fill>
```

Graphically, the index references can be shown like this:



3.7.4.5 Custom Table Style

L	M	N	O
Column1	Column2	Column3	Column4
A	381.41	513.27	357.29
B	470.33	411.76	723.52
C	624.47	287.49	365.38
D	17.77	775.36	969.69

This range of cells is a Table object with a custom Table style applied. The table definition in table1 specifies which table style is applied, and which aspects of the table style definition are 'turned on' and should be applied:

```
<table  id="2" name="Table11" displayName="Table11" ref="L20:O24"
totalsRowShown="0">
    <tableStyleInfo name="TableStyleMedium10 - Custom" showFirstColumn="0"
showLastColumn="0" showRowStripes="1" showColumnStripes="0"/>
</table>
```

The <tableStyleInfo> element indicates that this Table uses the "TableStyleMedium10 - Custom" style and that "first column", "last column", and "column stripes" formatting are OFF. It also indicates that "row stripes" formatting is ON.

Here is the "TableStyleMedium10 - Custom" definition in the Styles part:

```
    <tableStyles count="1" defaultTableStyle="TableStyleMedium9"
defaultPivotStyle="PivotStyleLight16">
        <tableStyle name="TableStyleMedium10 - Custom" pivot="0" count="7">
            <tableStyleElement type="wholeTable" dxfId="6"/>
            <tableStyleElement type="headerRow" dxfId="5"/>
            <tableStyleElement type="totalRow" dxfId="4"/>
            <tableStyleElement type="firstColumn" dxfId="3"/>
            <tableStyleElement type="lastColumn" dxfId="2"/>
            <tableStyleElement type="firstRowStripe" dxfId="1"/>
            <tableStyleElement type="firstColumnStripe" dxfId="0"/>
        </tableStyle>
    </tableStyles>
    <colors/>
</styleSheet>
```

Note that even though column stripes are defined for this table style, they are not used for this instance of the table.

The header row formatting for this table is defined by the 5th <dxf> definition:

```
        <dxf>
            <font>
                <b/>
                <color theme="0"/>
            </font>
            <fill>
                <patternFill patternType="solid">
                    <fgColor theme="5"/>
                    <bgColor theme="5"/>
                </patternFill>
            </fill>
            <border>
                <bottom style="medium">
```

```
                        <color theme="1"/>
                    </bottom>
                </border>
            </dxf>
```

This formatting indicates that for the header row of this table, the font is bold face and uses a themed color; the fill is solid and uses a themed color; and there is a bottom border on the cells.

3.8 Worksheet Metadata

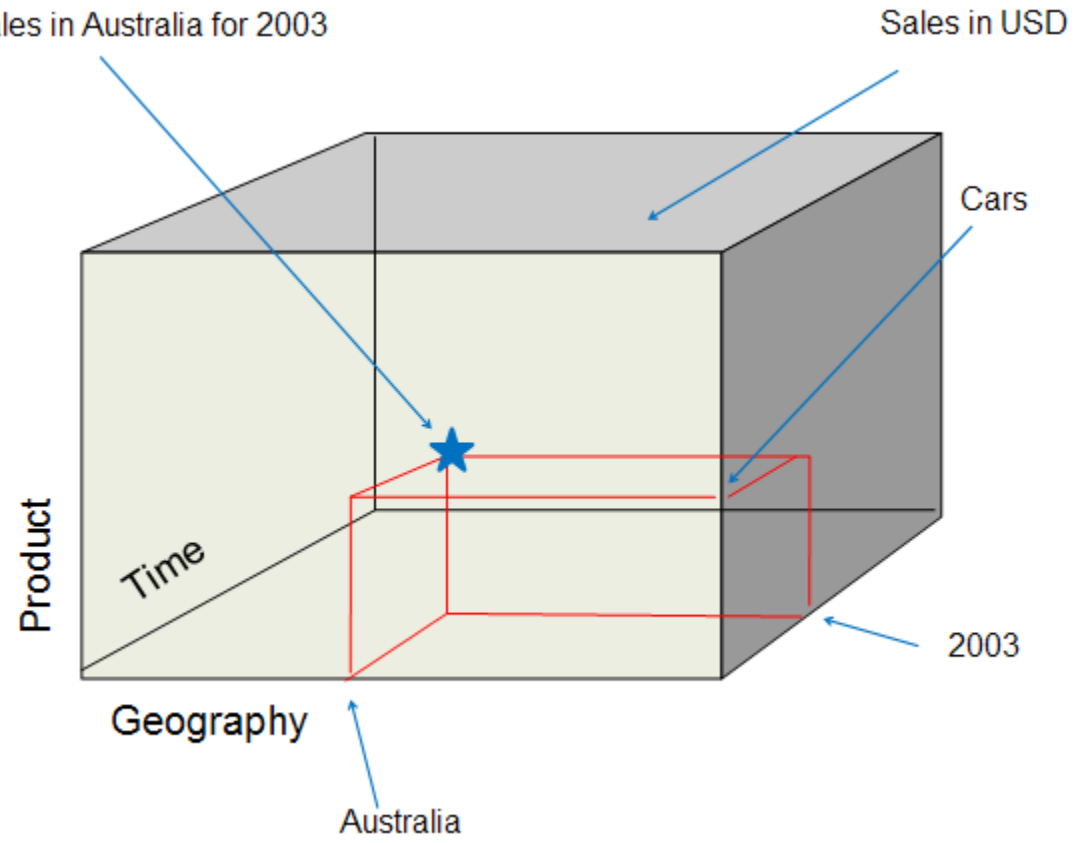
3.8.1 Overview

Value and cell metadata are additional properties that can be associated with a particular cell or value. Cell metadata properties can be carried along with the cell as it moves (e.g., via insert, shift, copy/paste, merge, or unmerge) and value metadata properties can be propagated along with the value as it is referenced in formulas.

All of this metadata is stored separately in the metadata.xml part in the workbook.

While the architecture of this feature allows for future extensions, only MDX metadata—metadata that is associated with a particular cube function and it's results—is currently defined. For example, if a CUBEMEMBER function call is used to identify a particular member in an OLAP cube, then the metadata would express the OLAP connection name, the mdx expression identifying that member, and various operational attributes of that metadata (e.g., whether it propagates through formula assignment, shifts with the cell when the cell moves locations in the grid, and so on).

3.8.1.1 OLAP Cube Review



Consider the 3-dimensional OLAP cube above. The three *dimension*s of the cube are "Product", "Geography", and "Time". "Sales Amount" is the *measure* being summarized, and is often considered an additional dimension of the cube. OLAP cubes can be N-dimensional, while this one has three dimensions.

Within each dimension are *hierarchies*, or ways of organizing the dimension into various levels of granularity. For example, within the Time dimension there can exist the Calendar Year / Quarter / Month / Day hierarchy. Likewise, the Time dimension can also have the Fiscal Year / Quarter / Month / Day hierarchy. Each of Year / Quarter / Month / Day represents *levels* in the hierarchy. '2003' is considered a *member* of the 'Year' level within the hierarchy. Likewise, the Product dimension can have multiple hierarchies. A hierarchy could be constructed based on the type of product while another hierarchy could be constructed based on the color of the product.

In the example above, picking a member from one dimension would be visualized as a slice through the cube. For example, picking 'Australia' from the Geography dimension could be a relatively thick slice of the cube, if there were many levels underneath 'Country', like 'State', 'City', and 'PostalCode'. Picking a member from Geography that is more granular than 'Australia" results in a thinner slice of the cube in the Geography dimension, because now some of Australia will have been omitted from the data.

A *tuple* is the intersection of two or more members from distinct dimensions. In the example above, three members from three dimensions are expressed:

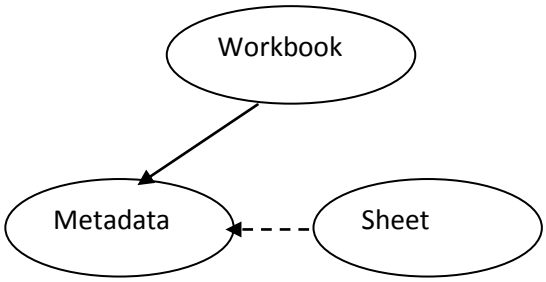
1. From Geography we have [Geography].[Country].&[Australia]
2. From Product we have [Product].[Cars].children
3. From Time we have [Time].[Calendar].[Calendar Year].&[2003]

3.8.1.2 OLAP Function Summary

There are seven recognized "CUBE" functions that can be used in cell formulas. These functions enable formulas in any cell to fetch data from Analysis Services. Specifically, the functions can fetch any member, set, aggregated value, property, or KPI from the OLAP cube. Because it is formula-driven, the layout of this data is as flexible as cells and formulas. The OLAP data can be placed anywhere on the spreadsheet, intermingled with other local calculations or within other formulas.

The function names are: CUBEKPIMEMBER, CUBEMEMBER, CUBEMEMBERPROPERTY, CUBERANKEDMEMBER, CUBESET, CUBESETCOUNT, and CUBEVALUE.

3.8.2 File Architecture – Relationships



The workbook holds the relationship to the metadata part, and cells within a sheet reference the items in the metadata part.

3.8.3 Example

In the following example, Cube functions are used to build up a report of internet sales by country, for all products, for the calendar years 2003 and 2004.

3.8.3.1 Illustration

	A	B	C	D
1			Internet Sales Amount	
2			CY 2003	CY 2004
3			All Products	
4				
5	Countries	6	2003 Sales	2004 Sales
6	United States		$2,838,512.36	$3,324,031.16
7	Australia		$3,033,784.21	$2,563,884.29
8	United Kingdom		$1,298,248.57	$1,210,286.27
9	Germany		$1,058,405.73	$1,076,890.77
10	France		$1,026,324.97	$922,179.04
11	Canada		$535,784.46	$673,628.21

3.8.3.1.1 Function Summary

CUBEMEMBER(*connection*, *member-expression*, *caption*) returns a member in the cube (e.g., Bicycles, Cars, All Products, CY 2004) (member can be a tuple)

CUBESET(*connection*, *set-expression*, *caption*, *sort-order*, *sort-by*) returns a set of members (e.g., all Countries)

CUBERANKEDMEMBER(*connection*, *set-expression*, *rank*, *caption*) returns one member of the referenced set (e.g., Australia)

CUBEVALUE(*connection*, *member-expression-1*, *member-expression-2*, …) returns the aggregate summarized value for the intersection of members specified.

3.8.3.1.2 Walk Through

C1 contains a CUBEMEMBER function call specifying the "Internet Sales Amount" member from the Measures dimension. C2 contains a CUBEMEMBER function call specifying "CY 2003" from the Date dimension. D2 contains a similar function specifying "CY2004" from the Date dimension. C3 contains a CUBEMEMBER function call specifying "All Products" from the Product dimension. Each of these cells contain simple string values (e.g., "All Products" in C3), and each of these cells is associated with mdx metadata which specifies the mdx expression identifying a particular member of a particular dimension (e.g., [Measures].[Internet Sales Amount]).

A5 contains a CUBESET function call specifying a set of members. Additionally, the CUBESET function call allows for specifying a caption for the cell ("Countries"), a sort order for sorting the set (in this case, "2" corresponds to descending), and a sort by field (in this case the set will be sorted by the member as expressed in the mdx associated with cell D5, labeled "2004 Sales"). Finally, it should be noted that CUBESET returns a set of members, not just a single member.

Cells A6:A11 use the CUBERANKEDMEMBER function to return the individual members, by rank, returned from the CUBESET function call in A5. For example, A6 uses the "xlextdat9 Adventure Works" connection to connect to the OLAP cube, and addresses the first member (because "ROW(A1)" resolves to "1") in the set returned in A5.

Cell C6 uses the CUBEVALUE function to return measure data identified by intersecting the mdx expression found in A6 with the mdx expression found in C5 ("CY 2003 Internet Sales for All Products in the United States"). C7:C11 use similar CUBEVALUE function calls. D6:D11 involves similar functions as well, but using "CY 2004" instead.

The power of metadata in this example is that anytime a CUBE function argument referenced another cell, and that argument requires a set or member mdx expression, the mdx metadata for that referenced cell is returned to the calling function instead of the simple string value. For example, A6 contains a CUBERANKEDMEMBER function call, whose second argument is expecting a set of members. The reference for that argument is $A$5. Instead of using the A5's string value of "Countries" (which would result in a error), A5's mdx expression metadata is used instead, which returns a set. Similarly any of the CUBEVALUE function calls rely on cell references, where those cells contain mdx metadata used to pinpoint the measure data requested. Furthermore, each of the cells referenced by C6:D11, in turn reference other cells' mdx metadata. In this way, the mdx metadata is able to propagate through the formula calculation chain.

3.8.3.2 Worksheet Metadata XML

3.8.3.2.1 General Organization

```
<metadata>
  <metadataTypes/>
  <metadataStrings/>
  <mdxMetadata/>
  <valueMetadata/>
</metadata>
```

There are four general collections in the metadata part:

- metadataTypes - expresses various application runtime behaviors that apply to a set of metadata.
- metadataStrings - expresses supporting string resources for the metadata part. This includes the connection name to the OLAP cube as well as mdx expressions identifying members and sets.
- mdxMetadata - expresses the tuples in use in this workbook.
- valueMetadata - The block (bk) elements stored in valueMetadata are referenced from cells in the sheet definition (vm on the cell is an index (1-based) to a bk element). Each record in a block

references additional element collections in the metadata part to define fully the metadata associated with this particular record, and therefore the full metadata definition for a particular cell's value. The records in valueMetadata serve as the bridge between the metadata definitions and the cells or values in the sheet.

3.8.3.2.2 Metadata Behaviors

The metadata type expresses operations on cells that allow the metadata to remain associated with the cell. Operations not listed or set to '0' would cause the metadata to no longer be associated with the cell.

```
<metadataTypes count="1">
  <metadataType name="XLMDX" minSupportedVersion="120000" copy="1"
    pasteAll="1" pasteValues="1" merge="1" splitFirst="1"
    rowColShift="1" clearFormats="1" clearComments="1" assign="1"
    coerce="1"/>
</metadataTypes>
```

Regarding metadataTypes:

- count is the number of metadataType elements.
- type is a particular set of cell operations.

Regarding metadataType:

- name is the name of this particular metadata type.
- minSupportedVersion indicates the earliest version of the application which supports this metadata type.
- copy value of 1 indicates that this metadata will be copied to other cells when the cell is copied.
- pasteAll value of 1 indicates that this metadata will be pasted to another cell when 'paste all' is chosen during a copy/paste operation.
- pasteValues value of 1 indicates that this metadata will be pasted to another cell when only the values of the cell is pasted during a copy/paste operation.
- merge value of 1 indicates that when the cell is merged, the metadata associated with the cell remains.
- splitFirst value of 1 indicates that when a merged cell is split, the metadata associated with the merged cell is only applied to the first (from top left) cell resulting from the split.
- rowColShift value of 1 indicates that metadata associated with a cell remains after rows and columns are inserted, even when the cell is moved.
- clearFormats value of 1 indicates that the metadata remains after the cell has been cleared of all formatting.
- clearComments value of 1 indicates that the metadata remains after comments have been cleared from the cell.
- assign value of 1 indicates that the metadata propagates through formula assignment operations

- coerce value of 1 indicates that the metadata can be removed when the data type is coerced to another type.

3.8.3.2.3 Metadata Strings

This collection is a set of string resources for the metadata part. Most follow the format of an mdx expression. Connection names (to OLAP cubes) are also expressed here.

```
<metadataStrings count="12">
  <s v="xlextdat9 Adventure Works"/>
  <s v="[Measures].[Internet Sales Amount]"/>
  <s v="[Date].[Calendar].[Calendar Year].&amp;[2003]"/>
  <s v="[Date].[Calendar].[Calendar Year].&amp;[2004]"/>
  <s v="[Product].[Product Categories].[All Products]"/>
  <s v="[Customer].[Customer Geography].[All Customers].children"/>
  <s v="[Customer].[Customer Geography].[Country].&amp;[Australia]"/>
  <s v="[Customer].[Customer Geography].[Country].&amp;
    [United States]"/>
  <s v="[Customer].[Customer Geography].[Country].&amp;
    [United Kingdom]"/>
  <s v="[Customer].[Customer Geography].[Country].&amp;[Germany]"/>
  <s v="[Customer].[Customer Geography].[Country].&amp;[France]"/>
  <s v="[Customer].[Customer Geography].[Country].&amp;[Canada]"/>
</metadataStrings>
```

Regarding metadataStrings:

- count indicates the number of strings in the collection.
- s is the string container element
- v is the string value itself.

3.8.3.2.4 mdxMetadata

This collection expresses mdx metadata, and builds up the mdx members, sets, KPIs, and member properties.

valueMetadata records reference these records.

```
<mdxMetadata count="26">
  <mdx n="0" f="m">
    <t c="1">
      <n x="1"/>
    </t>
  </mdx>
```

```
      <mdx n="0" f="m">
        <t c="1">
          <n x="2"/>
        </t>
      </mdx>
      <mdx n="0" f="m">
        <t c="1">
          <n x="3"/>"
        </t>
      </mdx>
      <mdx n="0" f="m">
        <t c="1">

          <n x="3"/>
          <n x="4"/>
          <n x="9"/>
        </t>
      </mdx>
      <mdx n="0" f="v">
        <t c="4" ct="en-US">
          <n x="1"/>
          <n x="2"/>
          <n x="4"/>
          <n x="9"/>
        </t>
      </mdx>
```

```
      <mdx n="0" f="v">
        <t c="4" ct="en-US">
          <n x="1"/>
          <n x="3"/>
          <n x="4"/>
          <n x="10"/>
        </t>
      </mdx>
      <mdx n="0" f="v">
        <t c="4" ct="en-US">
          <n x="1"/>
          <n x="2"/>
          <n x="4"/>
          <n x="10"/>
        </t>
      </mdx>
      <mdx n="0" f="v">
        <t c="4" ct="en-US">
          <n x="1"/>
          <n x="3"/>
          <n x="4"/>
          <n x="11"/>
        </t>
      </mdx>
      <mdx n="0" f="v">
        <t c="4" ct="en-US">
          <n x="1"/>
          <n x="2"/>
          <n x="4"/>
          <n x="11"/>
        </t>
      </mdx>
      <mdx n="0" f="v">
        <t c="4" ct="en-US">
          <n x="1"/>
          <n x="3"/>
          <n x="4"/>
          <n x="6"/>
        </t>
      </mdx>
```

```
      <mdx n="0" f="s">
        <ms ns="5" c="3" o="d">
          <n x="1"/>
          <n x="3"/>
          <n x="4"/>
        </ms>
      </mdx>
      <mdx n="0" f="c">
        <ms ns="5" c="3" o="d">
          <n x="1"/>
          <n x="3"/>
          <n x="4"/>
        </ms>
      </mdx>
    </mdxMetadata>
```

Regarding mdxMetadata:

- count indicates the number of mdx statements in the collection.

Regarding mdx, which is a particular mdx statement:

- n indicates the index of the record in metadataStrings containing the connection name.
- f indicates the name of the calling cube function in the workbook.

Regarding t, which is an mdx tuple:

- c is the count of member expressions in the mdx tuple.

Regarding n:

- x is the index value into metadataStrings indicating the particular member expression for this dimension of the tuple expression.

For example, cell C5 has a CUBEMEMBER function call expressing the result of "Internet Sales Amount of All Products for CY 2003". In sheet1.xml, cell C5 has vm="5", which means it has an associated valueMetadata record whose index is "5". Looking ahead into the valueMetadata records, the 5th (1-based) record points to the 4th (zero-based) mdx collection in mdxMetadata.

The 5th mdx collection:

```
<mdx n="0" f="m">
  <t c="3">
    <n x="1"/>
    <n x="2"/>
    <n x="4"/>
  </t>
</mdx>
```

Where <n x="1"/> corresponds to the 1st position in the string store, namely

```
<s v="[Measures].[Internet Sales Amount]"/>
```

and where <n x="2"/> corresponds to the 2nd position in the string store, namely

```
<s v="[Date].[Calendar].[Calendar Year].&amp;[2003]"/>
```

and where <n x="4"/> corresponds to the 4th position in the string store, namely

```
<s v="[Product].[Product Categories].[All Products]"/>.
```

Therefore this data point in the cube is addressed by intersecting these three hierarchies, one in each dimension of the OLAP cube:

- [Measures].[Internet Sales Amount]
- [Date].[Calendar].[Calendar Year].[2003]
- [Product].[Product Categories].[All Products]

Regarding ms:

- ns is the index of the mdx set definition in the string store.
- c is the number of sort-by member indicies, in this case 3 because the set is sorted by the contents of D5, which happens to be a member defined by 3 coordinates in the cube.
- o indicates the order of the sort; in this case, 'descending'.
- n is the index indicating the mdx expressions in the string store used to identify the members used to define the sort-by set.

3.8.3.2.5 valueMetadata

This collection defines cell or value metadata information (depending on the value of metadataType's cellMeta)

```
<valueMetadata count="26">
  <bk>
    <rc t="1" v="0"/>
  </bk>
```

```
      <bk>
        <rc t="1" v="1"/>
      </bk>
      <bk>
        <rc t="1" v="2"/>
      </bk>
      <bk>
        <rc t="1" v="3"/>
      </bk>
      <bk>
        <rc t="1" v="4"/>
      </bk>
      <bk>
        <rc t="1" v="5"/>
      </bk>
      <bk>
        <rc t="1" v="6"/>
      </bk>
      <bk>
        <rc t="1" v="7"/>
      </bk>
      <bk>
        <rc t="1" v="8"/>
      </bk>
      <bk>
        <rc t="1" v="9"/>
      </bk>
      <bk>
        <rc t="1" v="10"/>
      </bk>
      <bk>
        <rc t="1" v="11"/>
      </bk>
      <bk>
        <rc t="1" v="12"/>
      </bk>
      <bk>
        <rc t="1" v="13"/>
      </bk>
      <bk>
        <rc t="1" v="14"/>
      </bk>
```

```
    <bk>
      <rc t="1" v="15"/>
    </bk>
    <bk>
      <rc t="1" v="16"/>
    </bk>
    <bk>
      <rc t="1" v="17"/>
    </bk>
    <bk>
      <rc t="1" v="18"/>
    </bk>
    <bk>
      <rc t="1" v="19"/>
    </bk>
    <bk>
      <rc t="1" v="20"/>
    </bk>
    <bk>
      <rc t="1" v="21"/>
    </bk>
    <bk>
      <rc t="1" v="22"/>
    </bk>
    <bk>
      <rc t="1" v="23"/>
    </bk>
    <bk>
      <rc t="1" v="24"/>
    </bk>
    <bk>
      <rc t="1" v="25"/>
    </bk>
  </valueMetadata>
```

Regarding valueMetadata:

- `count` indicates the number of metadata block records.

Regarding bk, which is a metadata block, and rc, which is a metadata record:

- `t` indicates the index of the metadataType record in metadataTypes collection.
- `v` is the index of metadata record value in the storage corresponding to record type.

Looking at the first block using the bk element, the type of metadata with which this record is associated is the first (and only) metadataType record, which is of type "XLMDX". This indicates that the v index is pointing to the 0th mdxMetadata record.

3.9 Pivot Table, Pivot Cache, and Common Types

3.9.1 Feature Overview

PivotTables display aggregated views of data easily and in an understandable layout. Hundreds or thousands of pieces of underlying information can be aggregated on row & column axes, revealing the meanings behind the data. PivotTable reports are used to organize and summarize your data in different ways. Creating a PivotTable report is about moving pieces of information around to see how they fit together. In a few gestures the pivot rows and columns can be moved into different arrangements and layouts.

A PivotTable object has a row axis area, a column axis area, a values area, and a report filter area. Additionally, PivotTables have a corresponding field list pane displaying all the fields of data which can be placed on one of the PivotTable areas.

Consider this source data:

	A	C	F	H	I	O	P	Q	Z	AA	AB
1	Customer Name	Country	City	Product Category	Product Subcategory	Year	Quarter	Month	Sales Amount	Tax Amount	Freight
2	Michele Raman	Australia	Bendigo	Bikes	Road Bikes	2001	3	September	3578.27	286.2616	89.4568
3	Misty Raji	Australia	Bendigo	Bikes	Road Bikes	2001	3	July	3578.27	286.2616	89.4568
4	Tabitha E Arthur	Australia	Bendigo	Bikes	Road Bikes	2001	3	July	3578.27	286.2616	89.4568
5	Clarence D Rai	Australia	Bendigo	Bikes	Mountain Bikes	2001	3	July	3399.99	271.9992	84.9998
6	Jimmy L Moreno	Australia	Bendigo	Bikes	Mountain Bikes	2001	3	July	3399.99	271.9992	84.9998
7	Rob Verhoff	Australia	Bendigo	Bikes	Mountain Bikes	2001	3	July	3374.99	269.9992	84.3748
8	Levi Sai	Australia	Bendigo	Bikes	Road Bikes	2001	3	July	3578.27	286.2616	89.4568
9	Logan Gonzales	Australia	Brisbane	Bikes	Road Bikes	2001	3	July	3578.27	286.2616	89.4568
10	Dalton J Lee	Australia	Brisbane	Bikes	Road Bikes	2001	3	August	3578.27	286.2616	89.4568

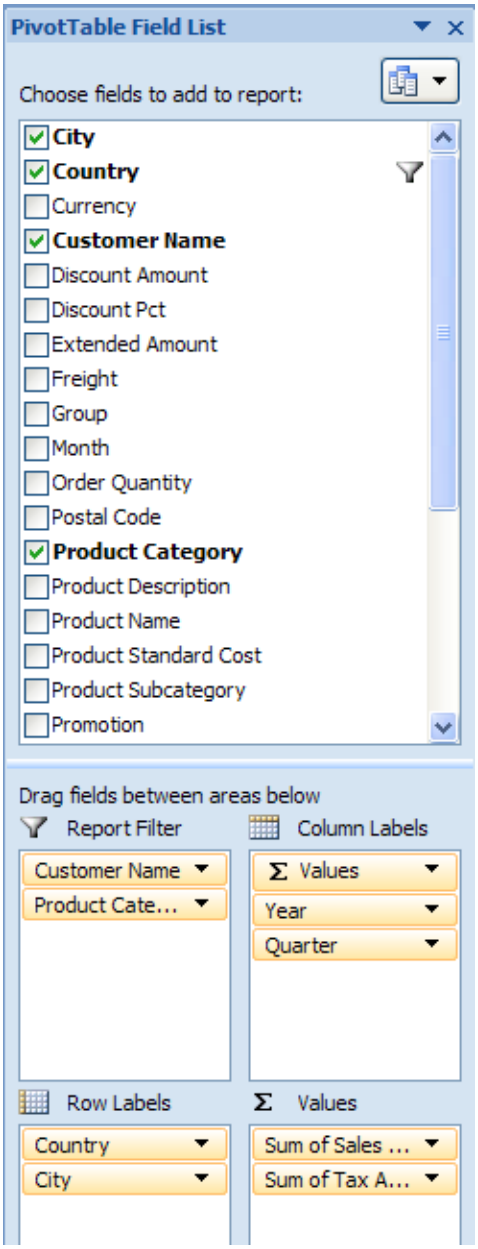
28	Willie She	Australia	Darlinghu	Bikes	Road Bikes	2001	3	September	3578.27	286.2616	89.4568
29	Alan Zhu	Australia	Darlinghu	Bikes	Road Bikes	2001	3	September	3578.27	286.2616	89.4568
30	Dawn R Tang	Australia	Darlinghu	Bikes	Road Bikes	2001	3	July	3578.27	286.2616	89.4568

This data can be consolidated and summarized in a PivotTable. One way to organize the information would look like this:

	A	B	C	D	E	F	G	H
1								
2		Customer Name	(All)					
3		Product Category	(All)					
4								
5			Column Labels					
6			Sum of Sales Amount			Sum of Tax Amount		
7			2001		2001 Total	2001		2001 Total
8		Row Labels	3	4		3	4	
9		**Australia**	**606184.7066**	**702862.4912**	**1309047.198**	**48494.7771**	**56229**	**104723.7771**
10		Goulburn	40580.8864	25047.89	65628.7764	3246.471	2003.8312	5250.3022
11		Warrnambool	28091.32	27863.04	55954.36	2247.3056	2229.0432	4476.3488
12		Port Macquarie	25746.9882	24463.05	50210.0382	2059.7591	1957.044	4016.8031
13		Wollongong	24691.33	25390.4282	50081.7582	1975.3064	2031.2343	4006.5407
14		Bendigo	24488.05	17484.79	41972.84	1959.044	1398.7832	3357.8272
15		Geelong	21113.06	21088.06	42201.12	1689.0448	1687.0448	3376.0896
16		Hobart	21088.06	6953.26	28041.32	1687.0448	556.2608	2243.3056
17		Lavender Bay	21063.06	21965.4382	43028.4982	1685.0448	1757.2351	3442.2799
18		Matraville	20909.78	6799.98	27709.76	1672.7824	543.9984	2216.7808

Here is the corresponding PivotTable field list:



3.9.2 File Architecture

The workbook points to (and owns the longevity of) the pivotCacheDefinition part, which in turn points to and owns the pivotCacheRecords part. The workbook also points to and owns the sheet part, which in turn points to and owns a pivotTable part definition, when a PivotTable is on the sheet (there can be multiple PivotTables on a sheet). The pivotTable part points to the appropriate pivotCacheDefinition which it is using. Since multiple PivotTables can use the same cache, the pivotTable part does not own the longevity of the pivotCacheDefinition.

The pivotTable part describes the particulars of the layout of the PivotTable on the sheet. It indicates what fields are on the row axis, the column axis, report filter, and values areas of the PivotTable. It also indicates

formatting information about the PivotTable. If conditional formatting has been applied to the PivotTable, that is also expressed in the pivotTable part.

The pivotCacheRecords part contains the underlying data to be aggregated. It is a cache of the source data. The pivotCacheDefinition part defines each field in the pivotCacheRecords part, including field name and information about the data contained in the field. The pivotCacheDefinition part also defines pivot items that are shared among the pivotTable and pivotRecords parts.

3.9.3 Example - Native with Range Source

3.9.3.1 Illustration

Consider the source data pictured in the overview section. There are 28 fields of data in total (some aren't shown). A corresponding PivotTable summary of the data can look like this:

	A	B	C	D	E	F	G
1							
2		Country	(All)				
3		State	(All)				
4		City	(All)				
5							
6		Sum of Sales Amount	Column Labels				
7			2001				2001 Total
8			3			3 Total	
9		Row Labels	July	August	September		
10		Bikes	209652.9046	222538.2892	173993.5128	606184.7066	606184.7066
11		Mountain Bikes	64424.81	60899.82	10174.97	135499.6	135499.6
12		Road Bikes	145228.0946	161638.4692	163818.5428	470685.1066	470685.1066
13		Grand Total	209652.9046	222538.2892	173993.5128	606184.7066	606184.7066

Regarding the layout of the PivotTable, notice that "Country", "State", and "City" are in the report filter area of the PivotTable. "Product Category" and "Product Subcategory" are on the row axis ("Bikes" belongs to the "Product Category" field and both "Mountain Bikes" and "Road Bikes" belong to the "Product Subcategory" field). On the column axis are "Year" ("2001"), "Quarter" ("3"), and "Month" ("July", "August", and "September") fields.

Row Grand Totals are turned on, and column Subtotals are turned on for Quarter and Year (if there was more than 1 quarter in the source data the Year Subtotal would be more interesting).

3.9.3.2 XML - pivotCacheDefinition part

The pivotCacheDefinition part defines each field in the source data, including the name, the string resources of the instance data (for shared items), and information about the type of data appearing in the field. Note: some of the "Customer Name" and "City" values have been removed to improve readability and reduce length.

```
<pivotCacheDefinition xmlns:r="…" r:id="rId1" refreshedBy="AnonUser"
  refreshedDate="2006-05-22T10:07:16" createdVersion="3"

        </cacheField>
        <cacheField name="Sales Amount" numFmtId="0">
          <sharedItems containsSemiMixedTypes="0" containsString="0"
            containsNumber="1" minValue="699.09820000000002"
            maxValue="3578.27"/>
        </cacheField>
        <cacheField name="Tax Amount" numFmtId="0">
          <sharedItems containsSemiMixedTypes="0" containsString="0"
            containsNumber="1"
            minValue="55.927900000000001" maxValue="286.26159999999999"/>
        </cacheField>
        <cacheField name="Freight" numFmtId="0">
          <sharedItems containsSemiMixedTypes="0" containsString="0"
            containsNumber="1" minValue="17.477499999999999"
            maxValue="89.456800000000001"/>
        </cacheField>
      </cacheFields>
    </pivotCacheDefinition>
```

In the context of pivotCacheDefinition:

- r:id indicates the relationship id pointing to the corresponding pivotCacheRecords part.
- refreshedBy indicates the username of whomever last refreshed the PivotCache.
- refreshedDate indicates when the PivotCache was last refreshed.
- createdVersion indicates the version of the producer which created the PivotCache.
- refreshedVersion indicates the version of the producer which last refreshed the PivotCache.
- minRefreshableVersion indicates the minimum version of the producer required to be able to refresh this PivotCache.

In the context of cacheSource:

- type indicates that data in a worksheet is the source for this PivotCache.
- worksheetSource identifies the particular location of the source data. In this case, it is a named range whose name is "Table1".

In the context of cacheFields, which is a collection of all the field definitions in the source data:

- cacheField indicates the name of the field and provides number format information.

In the context of cacheField:

- sharedItems indicates various flags about the data in this field. Child elements express the values of the shared items.

In the context of sharedItems:

- containsSemiMixedTypes "1" indicates that this field contains text values possibly mixed with other types of values, this can contain blanks. In this example the value is "0".
- containsString value of "1" indicates that this field contains a text value. In this example, the value is "0".
- containsNumber value of "1" indicates that this field contains numeric values.
- containsInteger indicates that this field contains integer values.
- minValue indicates that this field's minimum value is "3".
- maxValue indicates that this field's maximum value is "3".
- s indicates string content for this item value (expressed in v).
- n indicates the numeric content for this item value (expressed in v).

If there are no shared items expressed for a particular field, then the values are expressed directly in the pivotCacheRecords part.

Items in the PivotCacheDefinition can be shared, in order to reduce the redundancy of those values, since they're referenced in multiple places across all the PivotTable parts. For example, a value might be part of a filter, it might appear on a row or column axis, and will appear in the pivotCacheRecords definition as well. However, because of the performance cost of creating the optimized shared items, items are only shared if they are actually in use in the PivotTable. Therefore, depending on user actions on the PivotTable layout, the pivotCacheDefinition and underlying PivotCacheRecords part may be updated.

3.9.3.3 XML - pivotCacheRecords part

This part expresses the underlying source data that the PivotTable is aggregating. (Note that the data has been trimmed down to two records to increase readability.)

```
<pivotCacheRecords … xmlns:r="…" count="2">
  <r>
    <x v="0"/>
    <s v="Pacific"/>
```

```
      <x v="0"/>
      <s v="Australia"/>
      <x v="0"/>
      <x v="0"/>
      <s v="3550"/>
      <x v="0"/>
      <x v="0"/>
      <s v="Road-150 Red, 62"/>
      <s v="This bike is ridden by race winners. Developed with the Adventure
Works Cycles professional race team, it has a extremely light heat-treated
aluminum frame, and steering that allows precision control."/>
      <s v="No Discount"/>
      <s v="No Discount"/>
      <s v="No Discount"/>
      <x v="0"/>
      <x v="0"/>
      <x v="0"/>
      <s v="Australian Dollar"/>
      <n v="1"/>
      <n v="3578.27"/>
      <n v="3578.27"/>
      <n v="0"/>
      <n v="0"/>
      <n v="2171.2941999999998"/>
      <n v="2171.2941999999998"/>
      <n v="3578.27"/>
      <n v="286.26159999999999"/>
      <n v="89.456800000000001"/>
    </r>
    <r>
      <x v="1"/>
      <s v="Pacific"/>
      <x v="0"/>
      <s v="Australia"/>
      <x v="0"/>
      <x v="0"/>
      <s v="3550"/>
      <x v="0"/>
      <x v="0"/>
      <s v="Road-150 Red, 44"/>
      <s v="This bike is ridden by race winners. Developed with the Adventure
Works Cycles professional race team, it has a extremely light heat-treated
aluminum frame, and steering that allows precision control."/>
```

```
        <s v="No Discount"/>
        <s v="No Discount"/>
        <s v="No Discount"/>
        <x v="0"/>
        <x v="0"/>
        <x v="1"/>
        <s v="Australian Dollar"/>
        <n v="1"/>
        <n v="3578.27"/>
        <n v="3578.27"/>
        <n v="0"/>
        <n v="0"/>
        <n v="2171.2941999999998"/>
        <n v="2171.2941999999998"/>
        <n v="3578.27"/>
        <n v="286.26159999999999"/>
        <n v="89.456800000000001"/>
      </r>
    </pivotCacheRecords>
```

In the context of pivotCacheRecords:

- r contains one record.

In the context of r:

- x is an index value referencing an item for this field, as defined in the pivotCacheDefinition part.
- s indicates that a value is being expressed inline in this record, and it is a string value.
- n indicates that a value is being expressed inline in this record, and it is a numeric value.

3.9.3.4 XML - pivotTable part

The pivotTable part is organized into 11 sections.

- Top-level attributes
- Location information
- Collection of Fields
- Fields on the row axis
- Items on the row axis (specific values)
- Fields on the column axis
- Items on the column axis (specific values)
- Fields in the report filter area
- Fields in the values area
- Style information
- This is what the shell of that structure looks like:

```
<pivotTableDefinition>
  <location/>
  <pivotFields/>
  <rowFields/>
  <rowItems/>
  <colFields/>
  <colItems/>
  <pageFields/>
  <dataFields/>
  </dataFields>
  <conditionalFormats/>
  <pivotTableStyleInfo/>
</pivotTableDefinition>
```

Each collection will now be addressed section by section.

3.9.3.4.1 Attributes on pivotTableDefinition

```
<pivotTableDefinition xmlns:sh="…" name="PivotTable2" cacheId="5"
  applyNumberFormats="0" applyBorderFormats="0" applyFontFormats="0"
  applyPatternFormats="0" applyAlignmentFormats="0"
  applyWidthHeightFormats="1"
  dataCaption="Values" updatedVersion="3" minRefreshableVersion="3"
  showCalcMbrs="0" useAutoFormatting="1" colGrandTotals="0"
  itemPrintTitles="1"
  createdVersion="3" indent="0" outline="1" outlineData="1"
  multipleFieldFilters="0">
```

In the context of pivotTableDefinition:

- name indicates the name of the PivotTable.
- cacheId references by Id a particular pivotCache in the pivotCaches collection listed in workbook.xml.
- applyNumberFormats value of "1" means to apply legacy autoformat number format properties.
- applyBorderFormats value of "1" means to apply legacy autoformat border format properties.
- applyFontFormats value of "1" means to apply legacy autoformat Font format properties.
- applyPatternFormats value of "1" means to apply legacy autoformat pattern format properties.
- applyAlignmentFormats value of "1" means to apply legacy autoformat alignment format properties.
- applyWidthHeightFormats value of "1" means to apply legacy autoformat width and height format properties.
- dataCaption is the name of the values area header cell which can appear in the PivotTable when two or more fields are in the values area.
- updatedVersion is the Pivot version that last updated the PivotTable.
- minRefreshableVersion is the minimum Pivot version required to update this PivotTable's Pivot Cache.

- showCalcMbrs indicates whether calculated members should be shown in the PivotTable. Only applies to PivotTables based on OLAP sources.
- useAutoFormatting indicates whether autoformatting has been applied to the PivotTable.
- colGrandTotals indicates whether column grand totals are on for this PivotTable.
- rowGrandTotals defaults to "1" and therefore is not written.
- itemPrintTitles flag indicating whether PivotItem names should be repeated at the top of each printed page.
- createdVersion The Pivot version that created the cache.
- indent indentation increment for compact row axis, which means the Report Layout is set to Compact Form.
- outline flag indicating whether new fields should have their outline form flag set to "1".
- outlineData flag indicating whether the values field in the PivotTable should be displayed in outline form.
- multipleFieldFilters flag indicating whether each field of a pivot table can have multiple filters set on it.

3.9.3.4.2 Location Information

Location provides details on where the PivotTable is located in the sheet.

```
<location ref="B6:G13" firstHeaderRow="1" firstDataRow="4"
  firstDataCol="1" rowPageCount="3" colPageCount="1"/>
```

In the context of location:

- ref the location of the PivotTable area, not including the report filter area.
- firstHeaderRow the first row of the PivotTable header, relative to the top left cell in ref value.
- firstDataRow the first row of the PivotTable values area, relative to the top left cell in ref value.
- firstDataCol the first column of the PivotTable values area, relative to the top left cell in ref value.
- rowPageCount indicates how many rows the report filter area will occupy, as fields are added to it, before taking up another column (there can be multiple rows and columns of fields in the report filter area). By default there is a single column of report filter fields and the fields occupy as many rows as there are fields..
- colPageCount indicates how many columns the report filter region will occupy, as fields are added to it, before taking up another row (there can be multiple rows and columns of fields in the report filter region). By default, there is a single column of report filter fields and the fields occupy as many rows as there are fields.

3.9.3.4.3 PivotTable Fields

This collection expresses item order and field information for each field associated with the PivotTable, whether shown in the PivotTable report or not. (Note that items have been removed from the "Customer Name" and "City" fields (1st and 6th) to shorten the example.)

```
<pivotFields count="28">
  <pivotField showAll="0" includeNewItemsInFilter="1">
    <items count="8">
      <item x="66"/>
      <item x="133"/>
      <item x="74"/>
      <item x="27"/>
      <item x="118"/>
      <item x="63"/>
      <item x="141"/>
      <item t="default"/>
    </items>
  </pivotField>
  <pivotField showAll="0" includeNewItemsInFilter="1"/>
  <pivotField axis="axisPage" showAll="0" includeNewItemsInFilter="1">
    <items count="2">
      <item x="0"/>
      <item t="default"/>
    </items>
  </pivotField>
  <pivotField showAll="0" includeNewItemsInFilter="1"/>
  <pivotField axis="axisPage" showAll="0" includeNewItemsInFilter="1">
    <items count="6">
      <item x="3"/>
      <item x="1"/>
      <item x="2"/>
      <item x="4"/>
      <item x="0"/>
      <item t="default"/>
    </items>
  </pivotField>
  <pivotField axis="axisPage" showAll="0" includeNewItemsInFilter="1">
    <items count="8">
      <item x="0"/>
      <item x="1"/>
      <item x="2"/>
      <item x="3"/>
      <item x="4"/>
      <item x="5"/>
      <item x="6"/>
      <item t="default"/>
    </items>
  </pivotField>
```

```
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField axis="axisRow" showAll="0" includeNewItemsInFilter="1">
        <items count="2">
          <item x="0"/>
          <item t="default"/>
        </items>
      </pivotField>
      <pivotField axis="axisRow" showAll="0" includeNewItemsInFilter="1">
        <items count="3">
          <item x="1"/>
          <item x="0"/>
          <item t="default"/>
        </items>
      </pivotField>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField axis="axisCol" showAll="0" includeNewItemsInFilter="1">
        <items count="2">
          <item x="0"/>
          <item t="default"/>
        </items>
      </pivotField>
      <pivotField axis="axisCol" showAll="0" includeNewItemsInFilter="1">
        <items count="2">
          <item x="0"/>
          <item t="default"/>
        </items>
      </pivotField>
      <pivotField axis="axisCol" showAll="0" includeNewItemsInFilter="1">
        <items count="4">
          <item x="1"/>
          <item x="2"/>
          <item x="0"/>
          <item t="default"/>
        </items>
      </pivotField>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
```

```
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField dataField="1" showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
      <pivotField showAll="0" includeNewItemsInFilter="1"/>
    </pivotFields>
```

In the context of pivotField:

- showAll flag indicating whether to show all items for this field.
- includeNewItemsInFilter Flag indicating if new items in the data source are included in the filter automatically after refresh when there was at least one hidden item for the field.
- axis indicates on which axis this field is shown on the PivotTable.
- dataField indicates that this field is in the values area of the PivotTable.

In the context of items, which is a listing of items (by index) in this field. The order in which the items are listed is the order they would appear on a particular axis (row or column, for example). In this example, the first field is "Customer Name" and the first item referenced here is <item x="66"/>,which references the value "Adam L Flores" in the pivotCacheDefinition. Therefore if one added "Customer Name" to the row axis, "Adam L Flores" would be the first row item listed.

In the context of item:

- t value of '`default`' indicates the subtotal or total item.

3.9.3.4.4 Row Axis Fields

This collection indicates which fields are on the row axis of the PivotTable.

```
    <rowFields count="2">
      <field x="7"/>
      <field x="8"/>
    </rowFields>
```

In the context of field within rowFields:

- x is a zero based index into the pivotFields collection.

For this example, this collection indicates that "Product Category" and "Product Subcategory" are on the row axis of the PivotTable, in that order.

3.9.3.4.5 Row Items

This collection is a listing of all the values on the row axis of the PivotTable. In the spreadsheet example, the item values are found in cells B10:B13. For example, "Bikes" is in B10, and corresponds to the first I element below.

```
<rowItems count="4">
  <i>
    <x/>
  </i>
  <i r="1">
    <x/>
  </i>
  <i r="1">
    <x v="1"/>
  </i>
  <i t="grand">
    <x/>
  </i>
</rowItems>
```

In the context of rowItems:

- i expresses all the values (for all fields) in one row of the row axis. There will be an I element for every row in the PivotTable.

In the context of i:

- r indicates how many fields/item values to "fill down" from the previous row item.

Note that the first item has no r explicitly written. Since a default of "0" is specified in the schema, for any item whose r is missing, a default value of "0" is implied.

In the context of x:

- v is a zero-based index referencing a pivotField item value. There will be as many x elements as there are item values in any particular row. Note that these x elements may not be explicitly written, but instead "inherited" from the previous row/i element, via the value of r. Note also that the pivotField items don't list values explicitly, but instead reference a shared item value in the pivotCacheDefinition part.

Note that the first instance of x has no attribute value v associated with it, so v's default value of "0" is implied.

Looking at the layout of the PivotTable in the spreadsheet for this example, "Bikes" is the first (and only) item value in the first row, in cell B10. In the XML defining the PivotTable row item values, the first I element corresponds to the first row. There is a single index element x. The first (and only) x element corresponds to

the first field on the row axis, namely "Product Category", and an index value of "0" indicates that the 0th item in the items collection for that pivotField definition is how to obtain the item value. Note that "Bikes" isn't explicitly listed as a value here, but instead the 0th item is an index to this field's shared items collection in the pivotCacheDefinition part.

For the second row, there are two item values, one item value (Bikes) from the first field in that row (Product Category) and one item value (Mountain Bikes) from the second field in that row (Product Subcategory). In the PivotTable, the first item value "Bikes" is hidden from view. In the XML for this example, the second I element expresses both item values for this row. The first item value "Bikes" is expressed implicitly, because the value of r on the second i element is '1', indicating that the first item value from the previous row will be reused again as the first item value for the current row. The second item value is expressed explicitly via the x element under the second i element. The index of '0' indicates that the 0th item in the pivotField element for that field is how to obtain the item value. Note again that the 0th item is itself an index into this field's shared items collection in the pivotCacheDefinition part.

The item values for the third row can be discovered in a similar way, so will not be discussed in detail here.

In the context of item:

- t value of 'default' indicates a grand total as the last row item value.

3.9.3.4.6 Column Axis Fields

This collection indicates which fields are on the column axis of the PivotTable.

```
<colFields count="3">
  <field x="14"/>
  <field x="15"/>
  <field x="16"/>
</colFields>
```

In the context of field:

- x is a zero based index into the pivotFields collection defined in this part.

For this example, the collection indicates that "Year", "Quarter" and "Month" are on the column axis of the PivotTable, in that order.

3.9.3.4.7 Column Items

This collection is a listing of all the values on the column axis of the PivotTable. In this example, the item values are found in cells C6:H8. For example, "2001" / "3" / "July" values are in C7:C9. Those are the first column item values and are referenced by the first <i> element below.

```
<colItems count="5">
  <i>
    <x/>
    <x/>
    <x/>
  </i>
  <i r="2">
    <x v="1"/>
  </i>
  <i r="2">
    <x v="2"/>
  </i>
  <i t="default" r="1">
    <x/>
  </i>
  <i t="default">
    <x/>
  </i>
</colItems>
```

In the context of colItems:

- i expresses all the values (for all fields) in one column of the column axis. There will be an i element for every column in the PivotTable column area.

In the context of i:

- r indicates how many fields/item values to "fill right" from the previous column.

Note that the first item has no r explicitly written so the default value of "0" is implied.

In the context of x:

- v is a zero-based index referencing a pivotField item value. There will be as many x elements as there are item values in any particular column. Note that these x elements sometimes are not explicitly written, but instead "inherited" from the previous column/i element, via the value of r. Note also that the pivotField items don't list values explicitly, but instead reference a shared item value in the pivotCacheDefinition part.

Note that the first instance of x has no attribute value v associated with it, so v's default value of "0" is implied.

The first i collection represents all item values for the first column in the column axis area of the PivotTable. The first x in the first i corresponds to the first field in the columns area of the PivotTable, namely "Year". The implied index value of '0' on this x indicates that the item value for this first item in the column is the 0th item

for this pivotField. The 0th item for this pivotField is itself an index to an item value into this field's shared items collection in the pivotCacheDefinition part, namely "2001".

The item values corresponding to the second and third x elements can be found in the same way, arriving at "3" for the second item value, and arriving at "July" for the third item value for this first column.

The second i collection expresses all three item values for the second column in the column axis area. The r value of '2' indicates that the first two item values from the previous column will be repeated here, which means that the first item value for this second column will be "2001" again and the second item value for this second column will be "3". The third item value is expressed by the only x element under this second i element, and without further explanation is understood to reference the item value "August".

3.9.3.4.8 Report Filter Area Fields

This collection describes which fields are found in the report filter area of the PivotTable.

```
<pageFields count="3">
  <pageField fld="2" hier="0"/>
  <pageField fld="4" hier="0"/>
  <pageField fld="5" hier="0"/>
</pageFields>
```

In the context of pageField:

- fld is a zero-based index indicating the field to be on the report filter area.
- hier is an index of the OLAP hierarchy to which this belongs.

3.9.3.4.9 Values Area Fields

This collection describes which fields are found in the values area of the PivotTable.

```
<dataFields count="1">
  <dataField name="Sum of Sales Amount" fld="25" baseField="0" baseItem="0"/>
</dataFields>
```

In the context of dataField:

- name is the name of the values field.
- fld is the index of the field being summarized.
- baseField is the index of the base field when showDataAs calculation is in use.
- baseItem is the index of the base item when showDataAs calculation is in use.

3.9.3.4.10 PivotTable Style Information

Styles information is discussed in the informative section on spreadsheetML styles. Therefore the XML is provided for completeness, but will not be discussed here.

```
<pivotTableStyleInfo name="PivotStyleDark8" showRowHeaders="1"
  showColHeaders="1" showRowStripes="0" showColStripes="0"
  showLastColumn="1"/>
</pivotTableDefinition>
```

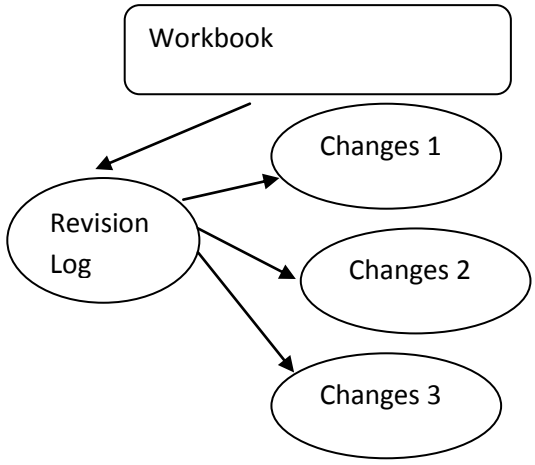
3.10 Shared Workbook Revisions

3.10.1 Overview

The Shared Workbooks architecture enables a spreadsheet application to record revisions made to a workbook (e.g., track changes), and is designed to enable multiple users to edit the same workbook at the same time. Therefore, the application needs to support the ability to read changes made by another user, and update its own state of the same workbook with those changes, even when those changes are made concurrently with other changes made by other users. Inevitably, there will be conflicts, and therefore merge conflict resolution should be supported by the runtime application.

This architecture supports the ability to track changes made by a single user as well.

3.10.2 How It Works



Relationship diagram

A Shared Workbook must have shared mode turned on. For unsaved workbooks, this will require a save, because revisions will be stored in the file.

Changes to the workbook are saved as Shared Workbook Revision Header parts within the document at each save or time interval specified.

A table summarizing the revision logs (revisionHeaders.xml) tracks when changes are made, who made them, and lists the relationship id to the specific Shared Workbook Revision Log part.

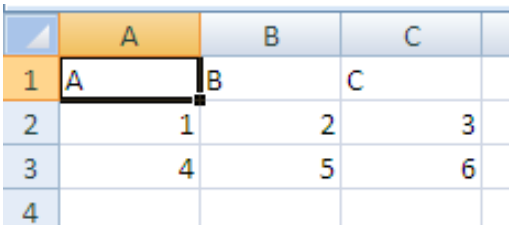
The application scans the summary table for new change logs and merges them into the workbook.

3.10.3 Example

Consider a series of edits made by different users.

3.10.3.1 First Edit

Starting with a blank workbook, the first user types "A, B, C" into A1:C1, and "1, 2, 3; 4, 5, 6" into A2:C3, like this:



Once the file is saved to disk after these edits, the summary table is updated and the revision log for this change is written.

3.10.3.1.1 Summary Revision Table

Contents of the Shared Workbook Revision Header part (revisionHeaders.xml).

Inside the summary table there is a revision header definition corresponding to the time of the edit:

```
<header guid="{902054C2-C7B5-48BA-BFB2-4D439D9758D6}"
  dateTime="2006-04-14T10:33:16" maxSheetId="4" userName="User 1"
  r:id="rId2" minRId="1" maxRId="11">
  <sheetIdMap count="3">
    <sheetId val="1"/>
    <sheetId val="2"/>
    <sheetId val="3"/>
  </sheetIdMap>
</header>
```

Notice that the user name, userName, and date and time stamp, dateTime, for the edit is stored along with an outline of the sheet structure. Use the r:id value of rId2 and then follow the relationship expressed in revisionHeaders.xml.rels. In this way, the corresponding Shared Workbook Revision Log can be located.

3.10.3.1.2 First Edit Revision Log

Inside the corresponding Shared Workbook Revision Log part is the following content:

```
<revisions xmlns="…" xmlns:r="…">
  <rcc rId="1" sId="1">
    <nc r="A1" t="inlineStr">
      <is>
        <t>A</t>
      </is>
    </nc>
  </rcc>
  <rcc rId="2" sId="1">
    <nc r="B1" t="inlineStr">
      <is>
        <t>B</t>
      </is>
    </nc>
  </rcc>
  <rcc rId="3" sId="1">
    <nc r="C1" t="inlineStr">
      <is>
        <t>C</t>
      </is>
    </nc>
  </rcc>
  <rrc rId="4" sId="1" eol="1" ref="A2:XFD2" action="insertRow"/>
  <rcc rId="5" sId="1">
    <nc r="A2">
      <v>1</v>
    </nc>
  </rcc>
  <rcc rId="6" sId="1">
    <nc r="B2">
      <v>2</v>
    </nc>
  </rcc>
  <rcc rId="7" sId="1">
    <nc r="C2">
      <v>3</v>
    </nc>
  </rcc>
  <rrc rId="8" sId="1" eol="1" ref="A3:XFD3" action="insertRow"/>
```

```
    <rcc rId="9" sId="1">
      <nc r="A3">
        <v>4</v>
      </nc>
    </rcc>
    <rcc rId="10" sId="1">
      <nc r="B3">
        <v>5</v>
      </nc>
    </rcc>
    <rcc rId="11" sId="1">
      <nc r="C3">
        <v>6</v>
      </nc>
    </rcc>
  </revisions>
```

rId is the revision Id, and indicates the order in which the particular revision should be applied.

sId indicates the sheet to which this revision applies.

rcc means "revision cell change"

nc means new cell, and is of type CT_Cell (see §3.2 for more information on the cell definition). Note that instead of using a shared string table, strings are expressed inline for these cells.

rrc means "revision row/column". Note that rrc can have an associated action, like insertRow (or deleteRow), which would cause a row to be inserted (or deleted) at that step in the series of revisions.

3.10.3.2 Second Edit

During the second edit, bold facing has been applied to A1:C1, and a formula has been applied to A4:C4 to sum the data in the table. For example, A4 contains =SUM(A2:A3).

	A	B	C
1	**A**	**B**	**C**
2	1	2	3
3	4	5	6
4	5	7	9

Once the file is saved to disk after these edits, the summary table is updated and the revision log for this change is written.

3.10.3.2.1 Summary Revision Table

Contents of the Shared Workbook Revision Header part (revisionHeaders.xml).

Inside the summary table there is a revision header definition corresponding to the time of the edit:

```
<header guid="{A3A5EE09-2092-433C-895D-77D5A15DC847}"
  dateTime="2006-04-14T10:34:10" maxSheetId="4" userName="User 2"
  r:id="rId3" minRId="12" maxRId="15">
  <sheetIdMap count="3">
    <sheetId val="1"/>
    <sheetId val="2"/>
    <sheetId val="3"/>
  </sheetIdMap>
</header>
```

This time the user name has been updated. Use the r:id value of `rId3` and then follow the relationship expressed in revisionHeaders.xml.rels. In this way, the corresponding Shared Workbook Revision Log can be located.

3.10.3.2.2 Second Edit Revision Log

Inside the corresponding Shared Workbook Revision Log part is the following content:

```
<revisions xmlns="…" xmlns:r="…">
  <rfmt sheetId="1" sqref="A1:C1" start="0" length="2147483647">
    <dxf>
      <font>
        <b/>
        </font>
    </dxf>
  </rfmt>
  <rrc rId="12" sId="1" eol="1" ref="A4:XFD4" action="insertRow"/>
  <rcc rId="13" sId="1">
    <nc r="A4">
      <f>SUM(A2:A3)</f>
    </nc>
  </rcc>
  <rcc rId="14" sId="1">
    <nc r="B4">
      <f>SUM(B2:B3)</f>
    </nc>
  </rcc>
```

```
    <rcc rId="15" sId="1">
      <nc r="C4">
        <f>SUM(C2:C3)</f>
      </nc>
    </rcc>
    <rcv guid="{34804977-BBD3-40C9-87A7-1779BEE2183C}" action="add"/>
  </revisions>
```

rfmt indicates a formatting revision

start and length indicate where to apply the formatting on the string

eol indicates that an insert is happening at the end of a list of data (end row)

rcv means "revision custom view", and indicates that a custom view is to be added.

3.10.3.3 Third Edit

During this editing session, column A has been inserted, and columns have been inserted between the data. Additionally, a row has been inserted between the data and the summary formula row, and at the top of the worksheet.

	A	B	C	D	E	F
1						
2		A		B		C
3		1		2		3
4		4		5		6
6		5		7		9
7						

Once the file is saved to disk after these edits, the summary table is updated and the revision log for this change is written.

3.10.3.3.1 Summary Revision Table

Contents of the Shared Workbook Revision Header part (revisionHeaders.xml).

```
  <header guid="{894981D2-DACF-4C1B-951C-EB199EA01DBF}"
    dateTime="2006-04-14T10:36:10" maxSheetId="4" userName="User 2"
    r:id="rId4" minRId="16" maxRId="20">
    <sheetIdMap count="3">
      <sheetId val="1"/>
      <sheetId val="2"/>
      <sheetId val="3"/>
    </sheetIdMap>
  </header>
```

Use the r:id value of rId4 and then follow the relationship expressed in revisionHeaders.xml.rels. In this way, the corresponding Shared Workbook Revision Log part can be located.

3.10.3.3.2 Third Edit Revision Log

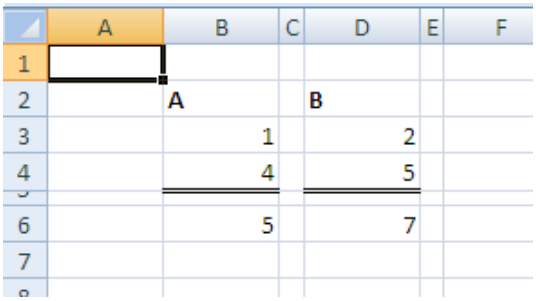
Inside the corresponding Shared Workbook Revision Log part is the following content:

```
<revisions xmlns="…" xmlns:r="…">
  <rrc rId="16" sId="1" ref="A1:XFD1" action="insertRow"/>
  <rrc rId="17" sId="1" ref="A1:A1048576" action="insertCol"/>
  <rrc rId="18" sId="1" ref="C1:C1048576" action="insertCol"/>
  <rrc rId="19" sId="1" ref="E1:E1048576" action="insertCol"/>
  <rrc rId="20" sId="1" ref="A5:XFD5" action="insertRow"/>
  <rcv guid="{34804977-BBD3-40C9-87A7-1779BEE2183C}" action="delete"/>
  <rcv guid="{34804977-BBD3-40C9-87A7-1779BEE2183C}" action="add"/>
</revisions>
```

rrc indicates a "revision to row/column". There are several row inserts and column inserts expressed here.

3.10.3.4 Fourth Edit

During this edit, a double-underscore cell border was applied to B4 and D4. Also, column F (the data titled "C") was deleted.



Once the file is saved to disk after these edits, the summary table is updated and the revision log for this change is written.

3.10.3.4.1 Summary Revision Table

Contents of the Shared Workbook Revision Header part (revisionHeaders.xml).

```
<header guid="{A478A962-DEB9-43AA-BB25-2C54AFA155F1}"
  dateTime="2006-04-14T10:37:14" maxSheetId="4" userName="User 2"
  r:id="rId5" minRId="21">
```

```
    <sheetIdMap count="3">
      <sheetId val="1"/>
      <sheetId val="2"/>
      <sheetId val="3"/>
    </sheetIdMap>
  </header>
```

Use the r:id value of rId5 and then follow the relationship expressed in revisionHeaders.xml.rels. In this way, the corresponding Shared Workbook Revision Log part can be located.

3.10.3.4.2 Fourth Edit Revision Log

Inside the corresponding Shared Workbook Revision Log part is the following content:

```
  <revisions xmlns="…" xmlns:r="…">
    <rrc rId="21" sId="1" ref="F1:F1048576" action="deleteCol">
      <rfmt sheetId="1" xfDxf="1" sqref="F1:F1048576" start="0" length="0"/>
      <rcc rId="0" sId="1" dxf="1">
        <nc r="F2" t="inlineStr">
          <is>
            <t>C</t>
          </is>
        </nc>
        <ndxf>
          <font>
            <b/>
            <sz val="11"/>
            <color theme="1"/>
            <name val="Calibri"/>
            <scheme val="minor"/>
          </font>
        </ndxf>
      </rcc>
      <rcc rId="0" sId="1">
        <nc r="F3">
          <v>3</v>
        </nc>
      </rcc>
      <rcc rId="0" sId="1">
        <nc r="F4">
          <v>6</v>
        </nc>
      </rcc>
      <rcc rId="0" sId="1">
        <nc r="F6">
```

```
            <f>SUM(F3:F4)</f>
          </nc>
        </rcc>
      </rrc>
      <rfmt sheetId="1" sqref="B4" start="0" length="0">
        <dxf>
          <border>
            <left/>
            <right/>
            <top/>
            <bottom style="double">
              <color auto="1"/>
            </bottom>
          </border>
        </dxf>
      </rfmt>
      <rfmt sheetId="1" sqref="D4" start="0" length="0">
        <dxf>
          <border>
            <left/>
            <right/>
            <top/>
            <bottom style="double">
              <color auto="1"/>
            </bottom>
          </border>
        </dxf>
      </rfmt>
    </revisions>
```

The first rrc element, with action="deleteCol" expresses that column F was deleted. Additionally, child collections of rrc contain all the column, formatting, and cell information (values and formulas) that was deleted as part of deleting column F.

xfDxf `true` means a whole row/column of formatting was affected.

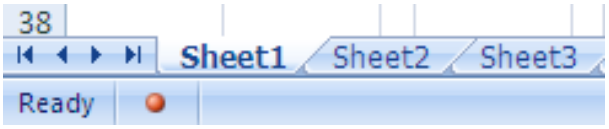
dxf `true` means cell change includes format change

The rfmt collections at the bottom of this XML indicate that borders were applied to B4 and D4.

3.10.3.5 Fifth Edit

Rename "Sheet1" to "Published Numbers".

Before:



After:

Once the file is saved to disk after these edits, the summary table is updated and the revision log for this change is written.

3.10.3.5.1 Summary Revision Table

Contents of the Shared Workbook Revision Header part (revisionHeaders.xml).

```
<header guid="{B0CB8BC9-63A4-4830-8821-E03C053BD326}"
  dateTime="2006-04-14T10:40:24" maxSheetId="4" userName="User 2"
  r:id="rId6" minRId="22">
  <sheetIdMap count="3">
    <sheetId val="1"/>
    <sheetId val="2"/>
    <sheetId val="3"/>
  </sheetIdMap>
</header>
```

Use the r:id value of `rId6` and then follow the relationship expressed in revisionHeaders.xml.rels. In this way the corresponding Shared Workbook Revision Log part can be located.

3.10.3.5.2 Fifth Edit Revision Log

Inside the corresponding Shared Workbook Revision Log part is the following content:

```
<revisions xmlns="…" xmlns:r="…">
  <rsnm rId="22" sheetId="1" oldName="[SharedWorkbook.xlsx]Sheet1"
  newName="[SharedWorkbook.xlsx]Published Numbers"/>
</revisions>
```

rsnm means "revision: sheet name".

oldName indicates the name of the sheet before renaming it.

newName indicates the name of the sheet after renaming it.

3.11 Query Tables

3.11.1 Overview

A *QueryTable object* is a range that is bound to an external data source. It is a cohesive range of cells in a sheet that share a common collection of properties and behaviors, separate from the connection itself. A QueryTable object can be associated with a cell range or a table definition.

3.11.2 Web Query Example

This example illustrates a range, B2:D6, QueryTable rendering, which is data-bound to a table found on http://www.msn.com, specifically the financial information table usually found on that page.

	A	B	C	D	E	F
1						
2		This table charts the key U.S. financial indices by their last				
3		Index	Last	Change		
4		Dow	11,642.65	2.88		
5		NASDAQ	2,320.74	-17.51		
6		S&P	1,322.85	-2.29		

3.11.2.1 QueryTable XML

```
<queryTable xmlns="…" name="www.msn" preserveFormatting="0"
  connectionId="1"
  autoFormatId="16" applyNumberFormats="0" applyBorderFormats="0"
  applyFontFormats="1" applyPatternFormats="1" applyAlignmentFormats="0"
  applyWidthHeightFormats="0"/>
```

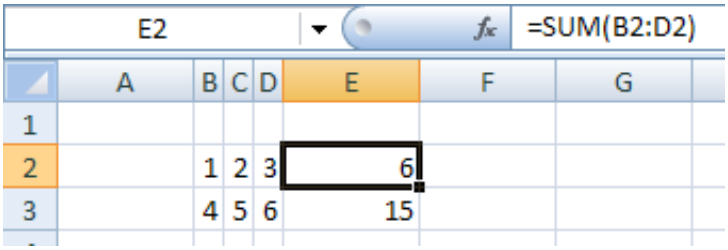
In the context of queryTable:

- name is the name of the QueryTable.
- preserveFormatting indicates whether to retain user-applied formatting after refresh or re-apply source data formatting.
- connectionId is the workbook connection's id.
- autoFormatId identifies (by implied index) the auto-format applied to the QueryTable.

All remaining attributes beginning with apply… indicate whether to apply this particular aspect of the auto-format definition.

3.11.3 Text Import Example

This example illustrates a range (B2:D3) QueryTable rendering which is data-bound to a text file. Notice that formulas are entered in E2:E3, the column directly to the right of the QueryTable range.



3.11.3.1 QueryTable XML

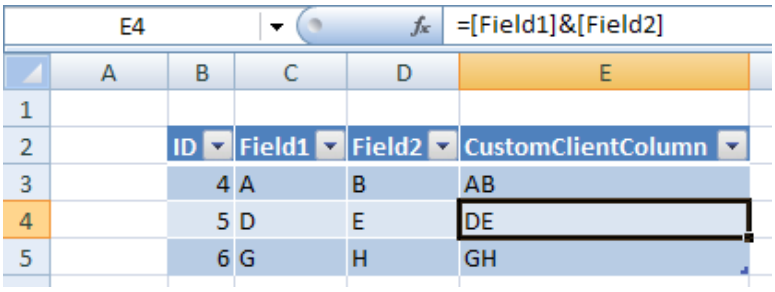
```
<queryTable xmlns="…" name="Text" refreshOnLoad="1" fillFormulas="1"
  removeDataOnSave="1" connectionId="3" autoFormatId="16"
  applyNumberFormats="0" applyBorderFormats="0" applyFontFormats="1"
  applyPatternFormats="1" applyAlignmentFormats="0"
  applyWidthHeightFormats="0"/>
```

In the context of queryTable:

- refreshOnLoad value of 1 indicates that this QueryTable should be refreshed when the workbook is opened.
- fillFormulas indicates that this QueryTable has immediately adjacent columns (which are not part of the QueryTable range) containing formulas that need to be filled down as the QueryTable grows and shrinks in size after refresh.
- removeDataOnSave indicates that the data in the worksheet resulting from the QueryTable refresh should be removed from the worksheet when saved and closed.

3.11.4 Access Table Example

This example demonstrates a QueryTable that is applied to a Table object. This data came from connecting to an Access database table with four fields: "ID", "Field1", "Field2", and "Field3". "Field3" has been deleted from the QueryTable in the worksheet below. Notice that a calculated column has been added to the Table, in the column titled "CustomClientColumn", which concatenates the values from "Field1" and "Field2".



3.11.4.1 QueryTable XML

```
<queryTable xmlns="…" name="Database1.accdb" connectionId="2"
  autoFormatId="16" applyNumberFormats="0" applyBorderFormats="0"
  applyFontFormats="0" applyPatternFormats="0" applyAlignmentFormats="0"
  applyWidthHeightFormats="0">
```

```
    <queryTableRefresh nextId="6" unboundColumnsRight="1">
      <queryTableFields count="4">
        <queryTableField id="1" name="ID" tableColumnId="1"/>
        <queryTableField id="2" name="Field1" tableColumnId="2"/>
        <queryTableField id="3" name="Field2" tableColumnId="3"/>
        <queryTableField id="5" dataBound="0" tableColumnId="4"/>
      </queryTableFields>
      <queryTableDeletedFields count="1">
        <deletedField name="Field3"/>
      </queryTableDeletedFields>
    </queryTableRefresh>
  </queryTable>
```

In the context of queryTableRefresh:

- nextId is the next available Id that can be assigned to a field. This is an optimization done for load/save, to avoid recalculating the value.
- unboundColumnsRight are the number of columns on the right side of the QueryTable that aren't data bound (don't come from the external data)

In the context of queryTableFields:

- Each of the queryTableField elements expresses information about one of the columns in the Table that is part of the QueryTable. For example, the right-most column's dataBound is set to `0`, indicating that this column is not bound to external data.

In the context of queryTable:

- queryTableDeletedFields collection expresses which fields returned by the connection have been deleted from the QueryTable. This is tracked so that the connection information does not have to be updated with which columns are no longer required.

3.12 External Connection

3.12.1 Overview

Many spreadsheet users want to be able to access data from external sources: databases, text files, web pages, XML web services, OLAP cubes. Typically, a spreadsheet application will provide abilities for the user to locate, browse, connect to, and query external data sources. Once the data source has been located, connected to, and queried, the resulting data must be rendered in the spreadsheet application, and made available for further analysis.

Data sources such as databases are made available for browsing and consumption via data-provider technologies. Typically, the data provider provides a standard interface for accessing the data, and removes the complexity introduced due to each database application's providing non-standard data access APIs. In this

way, OLEDB providers, for example, can be written for myriad database implementations, and a consumer can always use a single interface (defined by OLEDB) to access these disparate data sources.

A live connection to a data source is established by the application at runtime, and can only exist as a live connection while the application is running. There are two types of information about a particular connection:

- The information used to establish the connection.
- The information and properties about how the connection should be used and how the connection should behave in conjunction with the application.

Information about a connection can be supplied by the user as the connection is being established—for example, providing a password, picking a table, applying a filter, or setting behavioral properties such as whether to refresh the data when the workbook is opened and whether to store refreshed data in the worksheet when the workbook is saved.

Information about a connection can also be persisted in a connection file separately from the workbook file. In this way a directory or file share containing a variety of these connection files can be considered a library of data connections, for example.

Any time a connection is established, whether by using information from a connection file or by gathering the connection information directly from the user, a copy of the connection information is stored in the workbook.

Data providers and connection types discussed below are:

- ODBC
- OLEDB
- ADO
- DAO
- Text Import
- Web

The corresponding features in SpreadsheetML that render and analyze the data are:

- Query Table
- Table
- XML Map
- Pivot Table
- The CUBE* Functions

3.12.2 OLAP Connection

Below is a PivotTable that is rendering data from an OLAP source:

	A	B	C
1			
2		Row Labels	Amount
3		Current Year's Actuals	398755.69
4		Adjustment for Budget input	565238.13
5		Current Year's Budget	565238.13
6		Forecast	565238.13
7		Grand Total	398755.69
8			

3.12.3 Pivot XML fragment

In this example, the PivotTable data cache records /cacheSource@connectionId="2", which associates this PivotTable to the connection whose id="2" in the workbook connections part.

```
<pivotCacheDefinition … saveData="0" refreshedBy="Chad Rothschiller"
  refreshedDate="2006-04-13T16:02:14" backgroundQuery="1"
    createdVersion="3"
  refreshedVersion="3" minRefreshableVersion="3" recordCount="0">
  <cacheSource type="external" connectionId="2"/>
  <cacheFields count="2">
   <cacheField name="[Category].[Category Description]"
     caption="Category
     Description" numFmtId="0" hierarchy="1" level="1">
     <sharedItems count="4">
       <s v="[Category].[All Category].[Current Year's Actuals]"
         c="Current Year's Actuals"/>
```

3.12.4 Connection XML

Looking at the XML in the workbook connections part that describes the connection whose id="2":

```
<connection id="2" odcFile="
  c:\…\externalData.odc" keepAlive="1" name="externalData"
  description="FoodMart 2000 - Budget Planing" type="5"
  refreshedVersion="3" background="1">
  <dbPr connection="Provider=MSOLAP.2;Integrated Security=SSPI;Persist
    Security Info=True;Data Source=xlextdat8;Initial
      Catalog=AdamTest;Client
    Cache Size=25;Auto Synch Period=10000;MDX Compatibility=1"
      command="Budget" commandType="1"/>
  <olapPr sendLocale="1" rowDrillCount="1000"/>
</connection>
```

Attributes on the connection element express properties about the connection.

- odcFile indicates the location of the data connection file which was used to create this connection. Data connection files can be created on the local machine, on any network share, or any web location

whenever the connection is created so that the connection information can be reused if desired. The connection information is copied from the connection file into the spreadsheet. When a connection cannot be established, the spreadsheet application can check the external connection file to see if a newer definition of the connection is available.

- name indicates the friendly name of the connection. This name must be unique within a workbook.
- keepAlive indicates that the application should hold the connection open once established, instead of closing the connection after retrieving the data.
- type value of 5 indicates that this connection type is OLEDB.
- refreshedVersion indicates the version of the application which last refreshed this connection.
- background value of 1 indicates that background refresh (asynchronous refresh) is enabled. Note that this is not a guarantee that the connection will be refreshed asynchronously. Certain objects may require a connection to be refreshed either synchronously or asynchronously regardless of this setting.

Attributes on the dbPr element express additional properties on the connection.

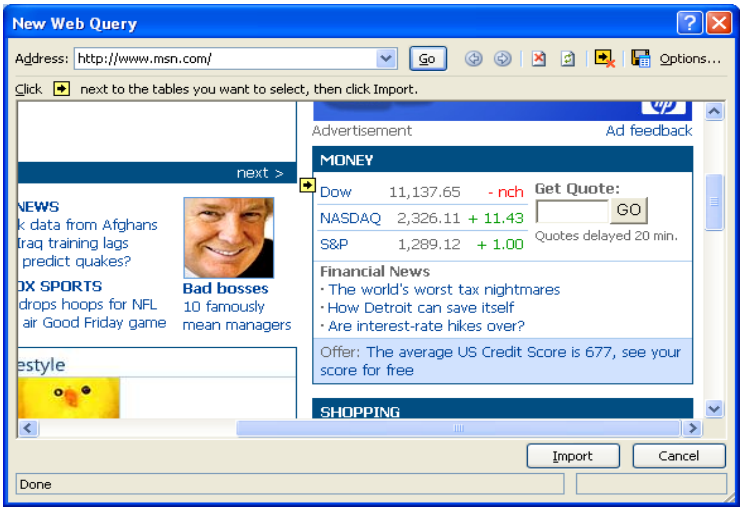
- connection expresses the connection string that is needed to establish a connection to the external data source.
- command can indicate a table name, a cube name, or an SQL expression requesting data.
- commandType indicates what kind of information is found in command: 1 means the value of command is the name of an OLAP cube.

Attributes on the olapPr element express properties that apply to connections to OLAP data sources.

- sendLocale value of 1 indicates that the client application should send its user interface language locale to the OLAP data provider in order to receive back from the server localized OLAP cube member string values.
- rowDrillCount is number of rows to return on a drill through request.

3.12.5 Web Query

A possible user interface for picking a web source is:



A possible rendering in the spreadsheet grid might be:

B	C	D
Web Query to MSN Money		
Dow	11,137.65	7.68
NASDAQ	2,326.11	11.43
S&P	1,289.12	1

3.12.6 QueryTable XML

The XML expressing the definition of the QueryTable indicates that it is using the connection whose Id value is 1 (connectionId):

```
<queryTable … name="msn" connectionId="1" autoFormatId="16"
  applyNumberFormats="0" applyBorderFormats="0" applyFontFormats="1"
  applyPatternFormats="1" applyAlignmentFormats="0"
applyWidthHeightFormats="0"/>
```

3.12.7 Connection XML

The workbook connection whose Id is 1 is expressed below.

```
<connection id="1" name="Connection" type="4" refreshedVersion="3"
  background="1" saveData="1">
  <webPr sourceData="1" parsePre="1" consecutive="1" xl2000="1"
    url="http://www.msn.com" htmlTables="1">
    <tables count="1">
      <x v="2"/>
    </tables>
  </webPr>
</connection>
```

Attributes and elements that have been previously discussed are not discussed here.

- type value of 4 indicates the connection is a web query connection.
- saveData value of 1 indicates that refreshed data will be kept in the sheet when saving the workbook. 0 indicates to remove the data from the workbook when saving the workbook.
- sourceData value of 1indicates to import and parse the XML data rather than consume the web page's HTML definition.
- parsePre value of 1 indicates that text in <PRE> tags is interpreted as tables.
- consecutive value of 1 means consecutive delimiters are treated as one delimiter
- url is the address indicating where to retrieve data for this query.
- htmlTables `true` means only import html tables

tables indicates which HTML table to import from the web page.

- v value of 2 indicates that the second table is the one to import.

3.12.8 Unused Connection

A connection can be expressed in a workbook, but not currently used. It remains until deleted by the user explicitly. This simply means that there is no object or feature in the workbook; that is referencing the connection.

3.12.9 ODBC

A database table imported to the grid, where the data provider is ODBC:

	A	B	C	D
1	ID	Field1	Field2	Field3
2	3	Foo	Bar	Goo
3	4	The	Quick	Brown
4	5	Fox	Jumped	Over
5	6	The	Lazy	Dog
6				

When a table object is used to render external data, it is associated with a QueryTable object to store the properties used when a range is associated with external data. Therefore, the Table object references the QueryTable name, which in turns references connectionId to identify the connection in the workbook connections part.

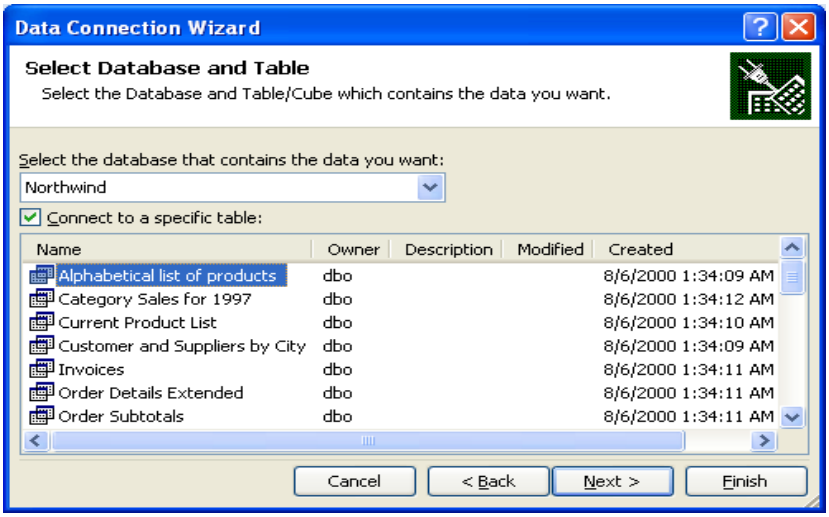
3.12.10 Connection XML

```
<connection id="4" name="Query from MS Access Database" type="1"
  refreshedVersion="3" background="1" saveData="1">
  <dbPr connection="DSN=MS Access
     Database;DBQ=E:\…\Database1.accdb;DefaultDir=E:\Documents and
     Settings\chadroth\Desktop;DriverId=25;FIL=MS
     Access;MaxBufferSize=2048;PageTimeout=5;"
       command="SELECT Table1.ID,
       Table1.Field1, Table1.Field2,
       Table1.Field3_x000d__x000a_FROM
       `E:\…\Database1.accdb`.Table1 Table1"/>
</connection>
```

- type value of 1 indicates ODBC connection type.
- command contents are an SQL select statement.

3.12.11 SQL

An implementation might use a data connection wizard to connect to a SQL table; for example:



The resulting data is rendered in the grid:

	A	B	C	D
1				
2		SQL Connection		
3		ShippedDate	OrderID	Subtotal
4		7/16/1996 0:00	10248	440
5		7/10/1996 0:00	10249	1863.4
6		7/12/1996 0:00	10250	1552.6
7		7/15/1996 0:00	10251	654.06
8		7/11/1996 0:00	10252	3597.9
9		7/16/1996 0:00	10253	1444.8
10		7/23/1996 0:00	10254	556.62
11		7/15/1996 0:00	10255	2490.5
12		7/17/1996 0:00	10256	517.8
13		7/22/1996 0:00	10257	1119.9
14		7/23/1996 0:00	10258	1614.88
15		7/25/1996 0:00	10259	100.8
16		7/29/1996 0:00	10260	1504.65
17		7/30/1996 0:00	10261	448
18		7/25/1996 0:00	10262	584

In this example, a table object is used to render external data, it is associated with a QueryTable object to store the properties used when a range is associated with external data. Therefore, the Table object references the QueryTable name, which in turns references `connectionId` to identify the connection in the workbook connections part.

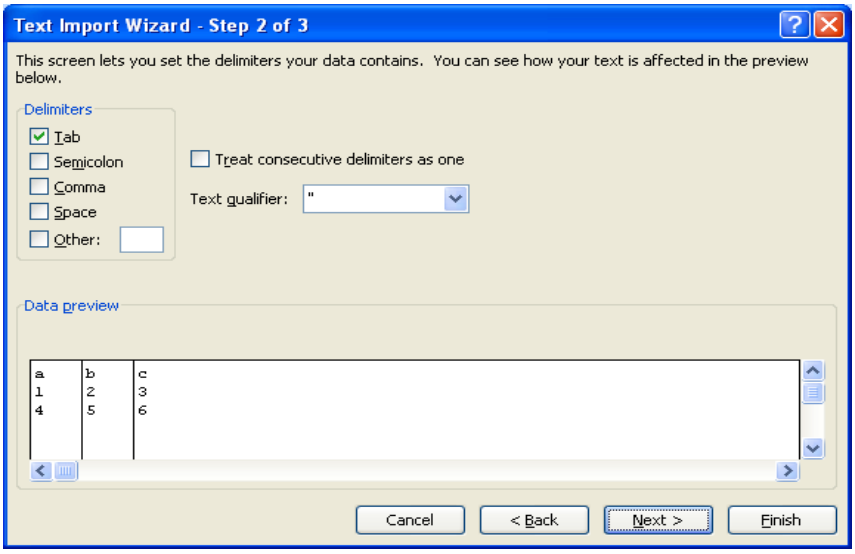
3.12.12 Connection XML

```
<connection id="6" odcFile="c:\…\xlextdat8 Northwind Summary of Sales by
  Year.odc" keepAlive="1"
  name="xlextdat8 Northwind Summary of Sales by Year"
  type="5" refreshedVersion="3" background="1" saveData="1">
  <dbPr connection="Provider=SQLOLEDB.1;Integrated Security=SSPI;
    Persist Security Info=True;Initial Catalog=Northwind;Data
    Source=xlextdat8;Use Procedure for Prepare=1;Auto
    Translate=True;Packet Size=4096;Workstation ID=CHADROTHO12;Use
    Encryption for Data=False;Tag with column collation when
    possible=False" command="&amp;quot;Northwind&amp;quot;.&amp;quot;dbo&amp;quot;
   .&amp;quot;Summary of Sales by Year&amp;quot;" commandType="3"/>
</connection>
```

- type value of 5 indicates that this connection is using an OLEDB data provider.
- commandType value of 3 specifies that a table name is in command
- command specifies a table name.

3.12.13 Text Import

Text Import settings:



Note that there are additional settings not pictured here.

The resulting data in the grid:

	A	B	C	D
1				
2		Text Import		
3		a	b	
4		1	2	
5		4	5	
6				

The range is associated with a QueryTable object. This query table definition references the connectionId used to retrieve the data.

3.12.14 Connection XML

```
<connection id="5" name="Text" type="6" refreshedVersion="3"
  background="1" saveData="1">…
  <textPr codePage="437" sourceFile="E:\ …\Text.txt">
    <textFields count="3">
      <textField type="text"/>
      <textField position="5"/>
      <textField type="skip" position="10"/>
    </textFields>
  </textPr>
</connection>
```

connection defines the connection

- type value of 6 indicates that this is a text import type of connection.

textPr expresses properties which are specific to text import connections.

- codePage value of 437 indicates that the text file is using the IBM PC (OEM) code page 437 character set.
- sourceFile indicates where the file is located.

textFields expresses information about the particular fields in the text file.

- delimited value of 1 (default) indicates that the text is delimited (variable length). Since this example uses the default value, it is not saved as part of the connection information.
- type indicates the data type (user-specified) of the particular field.
- position indicates the starting position of the field for fixed-width fields.
- thousands specifies the thousands separator character (not in this example, but of enough interest to mention).
- tab, space, comma attributes with values of 1 would flag these characters as delimiters (not in this example, but of enough interest to mention).

3.13 External Links

3.13.1 Overview

An *external link* is used to link a workbook to other workbook or to external data. The most frequent occurrence for linking a workbook to other workbooks has to do with formulas. In this case, a formula references a range or name defined in another workbook. Hyperlinks on cells and other spreadsheet objects are also considered an external link. OLE links are yet another technology used to link the workbook to another object. Finally, Dynamic Data Exchange (DDE) servers can be used to access external data. DDE servers are accessed through formulas in the workbook.

The goal of the way in which external links are saved is to always write the target source in a relationship file, so that external resources are easily discoverable in lightweight relationship XML rather than deep in the application's XML.

3.13.2 Formula Example

Consider cells B2 and C2 in the following worksheet, Sheet1:

	A	B	C
1		**Link to an external workbook range:**	**Link to an external workbook name:**
2		=SUM('C:\[Source.xlsx]Sheet1'!$A$1:$A$3)	='C:\Source2.xlsx'!NameInExternalWorkbook
3			
4		W3C Hyperlink	
5			

Here, the formulas themselves are displayed in the cells.

	A	B	C	D
1		**Link to an external workbook range:**	**Link to an external workbook name:**	
2		6	2	
3				
4		W3C Hyperlink		

Here, the results of the formulas are displayed in the cells.

The formula is expressed in Sheet1's XML, as shown in the following subclause.

3.13.3 Sheet XML

The corresponding content from Sheet1.xml is:

```
<worksheet …>
  <dimension ref="B1:C4"/>
  <sheetViews>
    <sheetView tabSelected="1" workbookViewId="0">
      <selection activeCell="B2" sqref="B2"/>
    </sheetView>
  </sheetViews>
  <sheetFormatPr defaultRowHeight="15"/>
  <cols>
    <col min="1" max="1" width="1.7109375" customWidth="1"/>
  </cols>
  <sheetData>
    <row r="1" spans="2:3" customFormat="1" ht="9" customHeight="1"/>
    <row r="2" spans="2:3" customFormat="1">
      <c r="B2">
        <f>SUM([1]Sheet1!$A$1:$A$3)</f>
        <v>6</v>
      </c>
      <c r="C2">
        <f>[2]!NameInExternalWorkbook</f>
        <v>2</v>
      </c>
    </row>
    <row r="4" spans="2:3" customFormat="1">
      <c r="B4" s="1" t="s">
        <v>0</v>
      </c>
    </row>
  </sheetData>
  <hyperlinks>
    <hyperlink ref="B4" r:id="rId1"/>
  </hyperlinks>
  <printOptions/>
  <pageMargins left="0.7" right="0.7" top="0.75" bottom="0.75"
    header="0.3" footer="0.3"/>
  <headerFooter/>
</worksheet>
```

3.13.3.1 Cell B2

The formula expressed in cell B2 (cell B2 is the c element whose r="B2") is this:

```
SUM([1]Sheet1!$A$1:$A$3)
```

The external reference to another workbook in this case is tokenized to `[1]`. The value inside the brackets is a 1-based index to the externalReferences collection in the workbook part.

3.13.3.2 Cell C2

The formula expressed in cell C2 (cell C2 is the `c` element whose `r` is `C2`) is this:

```
[2]!NameInExternalWorkbook
```

The external reference to another workbook in this case is tokenized to `[2]`. The value inside the brackets is a 1-based index to the externalReferences collection in the workbook part.

3.13.3.3 Workbook XML

The corresponding content from workbook.xml is

```
<workbook …>
  <fileVersion lastEdited="4" lowestEdited="4" rupBuild="4012"/>
  <workbookPr defaultThemeVersion="123820"/>
  <bookViews>
    <workbookView xWindow="360" yWindow="270" windowWidth="18735"
      windowHeight="11445"/>
  </bookViews>
  <sheets>
    <sheet name="Sheet1" sheetId="1" r:id="rId1"/>
    <sheet name="Sheet2" sheetId="2" r:id="rId2"/>
    <sheet name="Sheet3" sheetId="3" r:id="rId3"/>
  </sheets>
  <externalReferences>
    <externalReference r:id="rId4"/>
    <externalReference r:id="rId5"/>
  </externalReferences>
  <calcPr calcId="122211"/>
  <webPublishing codePage="1252"/>
</workbook>
```

The workbook part's externalReferences collection indicates that there are two external workbook references in this workbook. The first supporting external workbook data cache, also stored in this workbook, can be found by following the relationship from the workbook whose Id value is `rId4`. The second supporting external workbook data cache, also stored in this workbook, can be found by following the relationship from the workbook whose Id value is `rId5`.

3.13.4 Workbook Relationships

The corresponding content from workbook.xml.rels is:

```
<Relationships xmlns="http://…/package/2006/relationships">
  <Relationship Id="rId8" Type="http://…/sharedStrings"
Target="sharedStrings.xml"/>
  <Relationship Id="rId3" Type="http://…/worksheet"
Target="worksheets/sheet3.xml"/>
  <Relationship Id="rId7" Type="http://…/styles" Target="styles.xml"/>
  <Relationship Id="rId2" Type="http://…/worksheet"
Target="worksheets/sheet2.xml"/>
  <Relationship Id="rId1" Type="http://…/worksheet"
Target="worksheets/sheet1.xml"/>
  <Relationship Id="rId6" Type="http://…/theme" Target="theme/theme1.xml"/>
  <Relationship Id="rId5" Type="http://…/externalLink"
    Target="externalLinks/externalLink2.xml"/>
  <Relationship Id="rId4" Type="http://…/externalLink"
    Target="externalLinks/externalLink1.xml"/>
  <Relationship Id="rId9" Type="http://…/calcChain" Target="calcChain.xml"/>
</Relationships>
```

These relationship expressions indicate that cell B2 is supported by the external workbook data cache located at `externalLinks/externalLink1.xml` in the package. These relationship expressions also indicate that cell C2 is supported by the external workbook data cache located at `externalLinks/externalLink2.xml` in the package.

3.13.5 Supporting Workbook Cache (Cell C2)

The corresponding content from externalLink2.xml is:

```
<externalLink …>
  <externalBook xmlns:r="http://schemas.openxmlformats.org
    /officeDocument/2006/relationships" r:id="rId1">
    <sheetNames>
      <sheetName val="Sheet1"/>
      <sheetName val="Sheet2"/>
      <sheetName val="Sheet3"/>
    </sheetNames>
    <definedNames>
      <definedName name="NameInExternalWorkbook"
        refersTo="='Sheet1'!$B$1"/>
    </definedNames>
```

```
      <sheetDataSet>
        <sheetData sheetId="0">
          <row r="1">
            <cell r="B1">
              <v>2</v>
            </cell>
          </row>
        </sheetData>
        <sheetData sheetId="1"/>
        <sheetData sheetId="2"/>
      </sheetDataSet>
    </externalBook>
  </externalLink>
```

Supporting workbook data caches store the top-level structure of the workbook (sheet names, defined names, cell table). Only the cells referenced are cached. This supporting workbook data cache indicates that the workbook being referenced by C2 has three sheets, whose names are "Sheet1", "Sheet2", and "Sheet3", and has a defined name of "NameInExternalWorkbook". Additionally, the cell table shows that cell B1 in this workbook is the cell being referenced. A copy of the cell table is stored locally, inside the workbook containing the external link.

The r:id="rId1" on the top level externalLink element indicates the Id of the relationship from the `externalLink2.xml` part, which indicates the location of the actual external workbook.

3.13.6 External Link (Cell C2)

The corresponding content from externalLink2.xml.rels is

```
  <Relationships …>
    <Relationship Id="rId1" Type="http://…/externalLinkPath"
      Target="file:///C:\Source2.xlsx" TargetMode="External"/>
  </Relationships>
```

This relationship indicates that the supporting workbook that C2 references resides on the local drive, at `c:\source2.xlsx`.

3.13.7 Supporting Workbook Cache (Cell B2)

The corresponding content from externalLink1.xml is:

```
<externalLink …>
  <externalBook xmlns:r="http://…/relationships" r:id="rId1">
    <sheetNames>
      <sheetName val="Sheet1"/>
      <sheetName val="Sheet2"/>
      <sheetName val="Sheet3"/>
    </sheetNames>
    <sheetDataSet>
      <sheetData sheetId="0">
        <row r="1">
          <cell r="A1">
            <v>1</v>
          </cell>
        </row>
        <row r="2">
          <cell r="A2">
            <v>2</v>
          </cell>
        </row>
        <row r="3">
          <cell r="A3">
            <v>3</v>
          </cell>
        </row>
      </sheetData>
      <sheetData sheetId="1"/>
      <sheetData sheetId="2"/>
    </sheetDataSet>
  </externalBook>
</externalLink>
```

This supporting workbook data cache indicates that the workbook being referenced by B2 has three sheets, whose names are "Sheet1", "Sheet2", and "Sheet3". Additionally, the cell table shows that cells A1, A2, and A3, whose values are 1, 2, and 3, respectively, in this workbook are being referenced. A copy of the cell table is stored locally, inside the workbook containing the external link.

The r:id="rId1" on the top level externalLink element indicates the Id of the relationship from the `externalLink1.xml` part, which indicates the location of the actual external workbook.

3.13.8 External Link (Cell B2)

The corresponding content from externalLink1.xml.rels is

```
<Relationships …>
  <Relationship Id="rId1" Type="http://…/externalLinkPath"
    Target="file:///C:\Source.xlsx" TargetMode="External"/>
</Relationships>
```

This relationship indicates that the supporting workbook that C2 references resides on the local drive, at `c:\source.xlsx`.

3.13.9 Hyperlink Example

Consider the following worksheet:

	A	B	C
1		**Link to an external workbook range:**	**Link to an external workbook name:**
2		=SUM('C:\[Source.xlsx]Sheet1'!$A$1:$A$3)	='C:\Source2.xlsx'!NameInExternalWorkbook
3			
4		W3C Hyperlink	
5			

Cell B4 contains a hyperlink, whose friendly name is "W3C Hyperlink", and whose target is "`http://www.w3.org/`".

3.13.10 Worksheet XML

See §3.13.3 for the full XML. Here is the snippet expressing the hyperlink information, whose collection appears immediately after the sheetData collection in this example.

```
<hyperlinks>
  <hyperlink ref="B4" r:id="rId1"/>
</hyperlinks>
```

The hyperlink XML indicates that cell B4 of this sheet has a hyperlink, whose target can be found by following the relationship whose Id="rId1" from the current sheet. The 'friendly' name of the hyperlink is stored in the cell definition.

3.13.11 Relationship

The corresponding content from sheet1.xml.rels is:

```
<Relationships …>
  <Relationship Id="rId1" Type="http://…/hyperlink"
    Target="http://www.w3.org/" TargetMode="External"/>
</Relationships>
```

This hyperlink points external to the workbook (TargetMode="External"), and the URL is found in the value of Target to be "`http://www.w3.org/`".

3.14 Volatile Dependencies

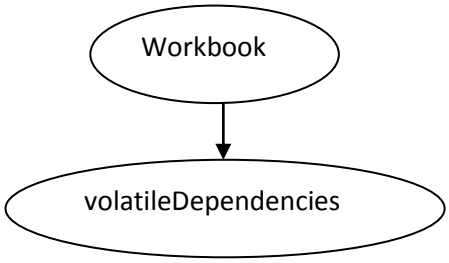
3.14.1 Overview

The volatile dependencies part provides a supporting cache of data for Real Time Data (RTD) and CUBE functions in the workbook. Both of these types of functions require connectivity to external servers to retrieve their data. For RTD functions, an RTD interface has been defined for how to provide (on the server side) and retrieve (on the client side) external data. Similarly, CUBE functions are able to access data in OLAP cubes. Each type of function has its own function syntax resulting in a specific piece of information being returned.

In the event that the server providing the data is unavailable, a spreadsheet application may want to cache the most recently retrieved values so that when recalculating the spreadsheet, calculated results may be acquired instead of errors.

The volatile dependencies part provides that cache of data and supporting information about these functions and their data servers and connections.

3.14.2 File Architecture - Relationships



The workbook holds the relationship to the volatile dependencies part.

3.14.3 Example

In this example, both a Real Time Data (RTD) function and CUBE functions are in use.

3.14.3.1 Illustration

	A	B
1	aaa: 672	
2		
3	Corporate	
4	$80,450,596.98	
5	Set	
6	#N/A	
7	#N/A	
8	Not Applicable	
9	Growth in Customer Base Goal	
10		

(values shown)

	A
1	=RTD("jrtdx.rtd",,"aaa")
2	
3	=CUBEMEMBER("xlextdat9 Adventure Works DW Adventure Works","[Department].[Departments].[Corporate]")
4	=CUBEVALUE("xlextdat9 Adventure Works DW Adventure Works",A3)
5	=CUBESET("xlextdat9 Adventure Works DW Adventure Works","[Customer].[Customer Geography].[All Customers].[United Kingdom].children","Set")
6	=CUBERANKEDMEMBER("xlextdat9 Adventure Works DW Adventure Works",$A$3,ROW(A1))
7	=CUBESETCOUNT(A3)
8	=CUBEMEMBERPROPERTY("xlextdat9 Adventure Works DW Adventure Works","[Product].[Product].[All Products].[Blade]","Class")
9	=CUBEKPIMEMBER("xlextdat9 Adventure Works DW Adventure Works","Growth in Customer Base",2)
10	

(functions shown)

3.14.3.2 volatileDependencies.xml

```
<volTypes xmlns="…">
  <volType type="realTimeData">
    <main first="jrtdx.rtd">
      <tp t="s">
        <v>aaa: 4447</v>
        <stp/>
        <stp>aaa</stp>
        <tr r="A1" s="1"/>
      </tp>
    </main>
  </volType>
  <volType type="olapFunctions">
    <main first="xlextdat9 Adventure Works DW Adventure Works">
      <tp t="e">
        <v>#N/A</v>
        <stp>1</stp>
        <tr r="A6" s="1"/>
        <tr r="A9" s="1"/>
        <tr r="A8" s="1"/>
        <tr r="A5" s="1"/>
        <tr r="A4" s="1"/>
        <tr r="A3" s="1"/>
      </tp>
    </main>
  </volType>
</volTypes>
```

3.14.3.2.1 RTD Supporting Data

`/voltypes/volType@type` indicates that the supporting information pertains to an RTD function call. Valid values are `realTimeData` and `olapFunctions`

/volTypes/volType/main@first indicates the ProgId of the RTD server. This value corresponds to the first argument of an RTD function in a worksheet.

/volTypes/volType/main/tp contains a listing of topics within the main topic. For the RTD function, this collection will express the remaining parameters of the function, and indicate the last known value and data type of that value.

/volTypes/volType/main/tp@t indicates the data type of the value associated with this topics. For this RTD example, the value is "aaa: 4447" whose data type is string.

/volTypes/volType/main/tp/v expresses the last known value of this RTD function, "aaa: 4447".

/volTypes/volType/main/tp/stp expresses the remaining topics, or function parameters, for this RTD function. Notice that in the example, the second parameter is left empty, and the third parameter is "aaa".

/volTypes/volType/main/tp/tr expresses the cells which are dependent on this particular set of topics, and which are associated with this supporting information.

3.14.3.2.2 Cube Function Supporting Data

Cube functions use the same persistence structure as the RTD supporting data, but the information is interpreted slightly differently. At a high level, main@first indicates the connection name, and the tr elements spell out the cells with cube function calls dependent on this connection. In most cases (when the <stp> value is equal to "1") the remaining information can be ignored.

/volTypes/volType/main@first indicates the connection name for the related cube functions.

/volTypes/volType/main/tp@t can be ignored when stp value is 1.

/volTypes/volType/main/tp/v contains an error value of "#N/A", which can be ignored when stp value is 1.

/volTypes/volType/main/tp/stp value of 1 indicates that all of the related cells with calling cube functions have been refreshed.

/volTypes/volType/main/tp/tr expresses the cells contain cube functions which are dependent on this connection, and which are associated with this supporting information.

3.15 Custom XML Mappings

3.15.1 Overview

With the pervasiveness of XML data structures and XML web services, it is appropriate for a spreadsheet application to consume XML data structures and render the data in the sheet grid. Furthermore it is appropriate and desirable for the spreadsheet application to be able to generate XML data structures. Finally, since XML is extensible, the kinds of XML structures that can be consumed or produced by a spreadsheet application should be as varied as the number of XML schemas that exist.

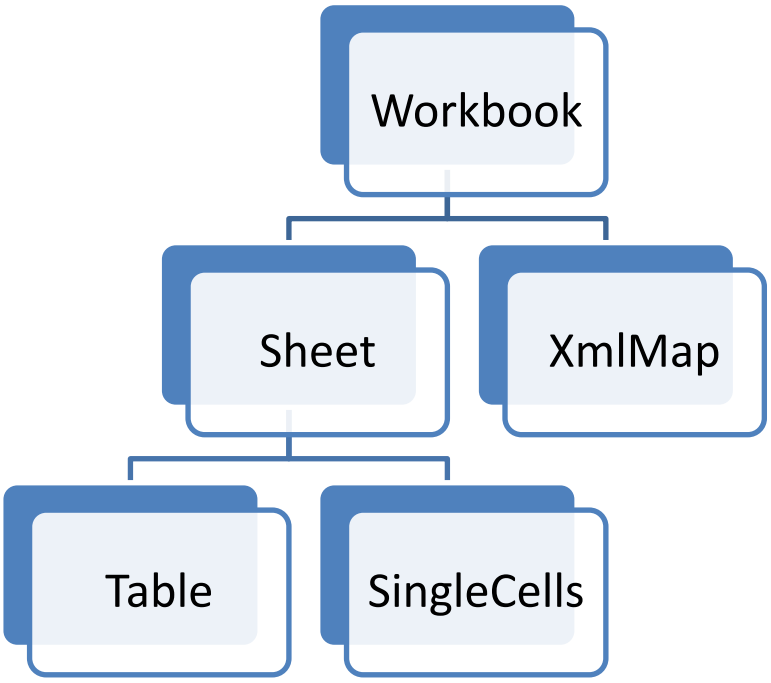
The XML Mapping feature enables adding arbitrary XML data structures and arbitrary XML schema definitions to the workbook, then mapping the various XML nodes to cells and ranges in the workbook. Once an XML Mapping is set up, the application is able to import and export XML instance structures according to the schema definition.

While the original schema or XML definition may reside on disk or at some file location outside the workbook, a copy of the schema is stored in the workbook.

Every time an XML instance or schema is added to the workbook, a new map object is created which ties together the schemas and where the various elements are mapped in the workbook.

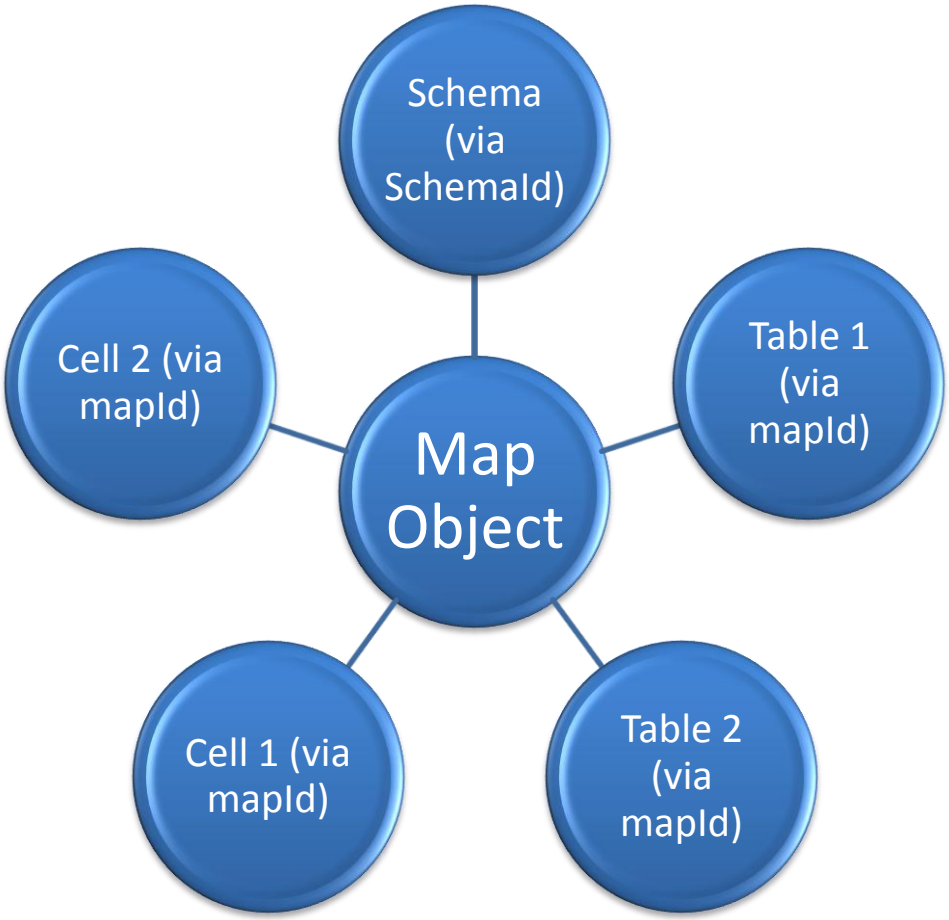
Additional properties are stored on each cell and each column of a Table that has an XML map association.

3.15.2 File Architecture - Relationships



The workbook owns sheets and the xmlMap definitions. Each sheet references Tables and single cells which are mapped to XML structures.

3.15.3 Conceptual Model

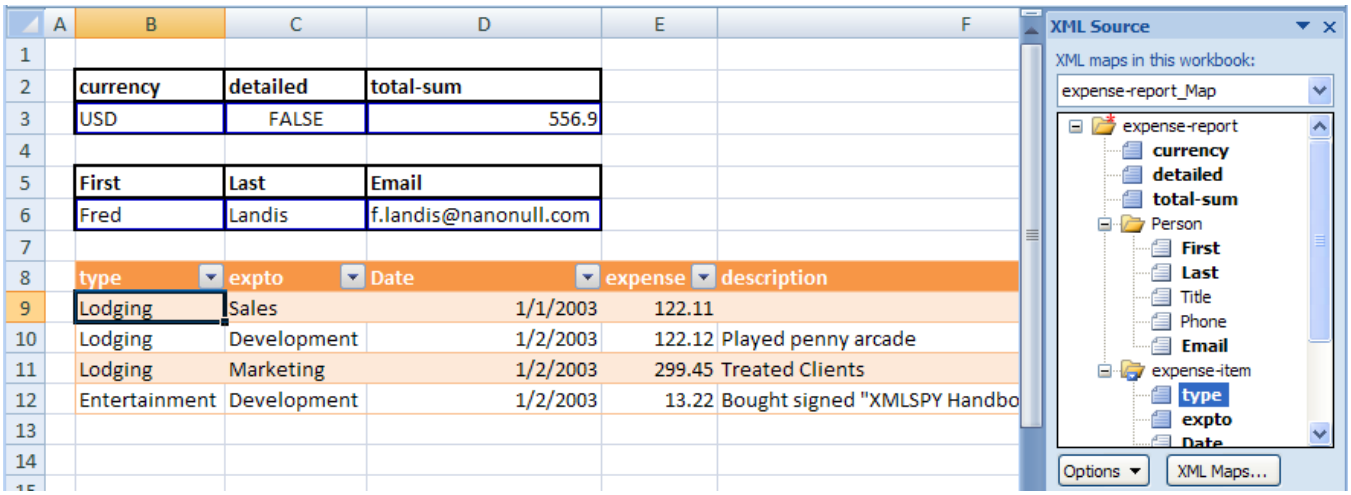


Conceptually all the objects reference a common Map Object, by `@id`. It is in this way that they come together into a single working feature that can import and export custom XML data.

3.15.4 Example

In this example both single cells and a Table are shown to have a data binding to an XML structure.

3.15.4.1 Illustration



currency	detailed	total-sum
USD	FALSE	556.9

First	Last	Email
Fred	Landis	f.landis@nanonull.com

type	expto	Date	expense	description
Lodging	Sales	1/1/2003	122.11	
Lodging	Development	1/2/2003	122.12	Played penny arcade
Lodging	Marketing	1/2/2003	299.45	Treated Clients
Entertainment	Development	1/2/2003	13.22	Bought signed "XMLSPY Handbo

The table in B8:G12 is also data bound to an XML mapping object. The first column, titled "type", is associated with the XML Map named "expense-report_Map", specifically the attribute identified by the xpath expression `/expense-report/expense-item@type` pointing into the corresponding XML structure. In similar fashion, each of the columns in the Table correspond with elements or attributes in the related XML Map structure.

Additionally, cells B3:D3 and B6:D6 are each bound to a single, non-repeating element or attribute from the same XML Map structure. For example, cell B3 corresponds to `/expense-report@currency`.

In this way XML instance structures can be refreshed into the cells and Table region, and XML instance structures can be generated from the data in those ranges of the spreadsheet. In other words, XML structures can be imported and exported to and from the worksheet via the XML Mapping feature.

3.15.4.2 The xmlMap XML

The xmlMaps part stores the custom schema that has been added to the workbook, and also stores the xmlMap definitions. There can be multiple schemas and xmlMaps in a single workbook.

```
<MapInfo SelectionNamespaces="">
    <Schema ID="Schema1">
        <xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
            <xsd:element nillable="true" name="expense-report">
                <xsd:complexType>
                    <xsd:sequence minOccurs="0">
                        <xsd:element minOccurs="0" nillable="true"
name="Person" form="unqualified">
                            <xsd:complexType>
                                <xsd:sequence minOccurs="0">
                                    <xsd:element minOccurs="0" nillable="true"
type="xsd:string" name="First" form="unqualified"></xsd:element>
```

```
                                    <xsd:element minOccurs="0" nillable="true"
type="xsd:string" name="Last" form="unqualified"></xsd:element>
                                    <xsd:element minOccurs="0" nillable="true"
type="xsd:string" name="Title" form="unqualified"></xsd:element>
                                    <xsd:element minOccurs="0" nillable="true"
type="xsd:string" name="Phone" form="unqualified"></xsd:element>
                                    <xsd:element minOccurs="0" nillable="true"
type="xsd:string" name="Email" form="unqualified"></xsd:element>
                                </xsd:sequence>
                            </xsd:complexType></xsd:element>
                        <xsd:element minOccurs="0" maxOccurs="unbounded"
nillable="true" name="expense-item" form="unqualified">
                            <xsd:complexType>
                                <xsd:all>
                                    <xsd:element minOccurs="0" nillable="true"
type="xsd:date" name="Date" form="unqualified"></xsd:element>
                                    <xsd:element minOccurs="0" nillable="true"
type="xsd:double" name="expense" form="unqualified"></xsd:element>
                                    <xsd:element minOccurs="0" nillable="true"
type="xsd:string" name="description" form="unqualified"></xsd:element>
                                    <xsd:element minOccurs="0" nillable="true"
name="Misc" form="unqualified">
                                        <xsd:complexType>
                                            <xsd:attribute name="misctype"
form="unqualified" type="xsd:string"></xsd:attribute>
                                        </xsd:complexType>
                                    </xsd:element>
                                </xsd:all>
                                <xsd:attribute name="type" form="unqualified"
type="xsd:string"></xsd:attribute>
                                <xsd:attribute name="expto" form="unqualified"
type="xsd:string"></xsd:attribute>
                            </xsd:complexType>
                        </xsd:element>
                    </xsd:sequence>
                    <xsd:attribute name="currency" form="unqualified"
type="xsd:string"></xsd:attribute>
                    <xsd:attribute name="detailed" form="unqualified"
type="xsd:boolean"></xsd:attribute>
                    <xsd:attribute name="total-sum" form="unqualified"
type="xsd:double"></xsd:attribute>
                </xsd:complexType>
            </xsd:element>
```

```
            </xsd:schema>
        </Schema>
        <Map ID="1" Name="expense-report_Map" RootElement="expense-report"
    SchemaID="Schema1" ShowImportExportValidationErrors="false" AutoFit="true"
    Append="false" PreserveSortAFLayout="true" PreserveFormat="true">
            <DataBinding FileBinding="true" DataBindingLoadMode="1"/>
        </Map>
    </MapInfo>
```

- /MapInfo@SelectionNamespaces ties the prefix to the actual namespace. This is used when writing xpath expressions at runtime against the XML instance structures, because the xpath expressions use namespace prefixes instead of the fully spelled out namespace.
- /MapInfo/Schema stores the schemas for a particular XML map object. There can be multiple <Schema> elements in a workbook, one for each XML map.
- /MapInfo/Schema@ID identifies the schema collection used to define a particular XML map object.
- /MapInfo/Map/@ID identifies the map object.
- /MapInfo/Map@Name is the friendly name of the map object.
- /MapInfo/Map@RootElement is the name of the root element of the XML instance (schemas can define more than one root node).
- /MapInfo/Map@SchemaID identifies which schema collection the map uses.
- /MapInfo/Map@ShowImportExportValidationErrors indicates that when an XML instance is imported or exported, the schema should be used to validate the instance, and schema errors should be shown to the user.
- /MapInfo/Map@AutoFit indicates that after refresh, all the cells should be 'best fitted'.
- /MapInfo/Map@Append means that when refreshed, don't discard existing data, but append new data to it.
- /MapInfo/Map@PreserveSortAFLayout indicates whether to keep filters on (Tables).
- /MapInfo/Map@PreserveFormat indicates whether to keep the cell formatting applied or re-apply based on schema data type.

3.15.4.3 The Table XML

The only difference with table definitions that are bound to XML is that @tableType="xml" and each column has an additional set of xml-specific properties, contained in the <xmlColumnPr> collection, which appears once for every column in the Table which has an XML data binding.

```
<table xmlns="http://schemas.openxmlformats.org/spreadsheetml/2006/5/main"
id="7" name="Table7" displayName="Table7" ref="B8:G12" tableType="xml"
totalsRowShown="0" connectionId="1">
    <autoFilter ref="B8:G12"/>
    <tableColumns count="6">
        <tableColumn id="1" uniqueName="type" name="type">
            <xmlColumnPr mapId="1" xpath="/expense-report/expense-item/@type"
xmlDataType="string"/>
```

```
            </tableColumn>
            <tableColumn id="2" uniqueName="expto" name="expto">
                <xmlColumnPr mapId="1" xpath="/expense-report/expense-item/@expto"
    xmlDataType="string"/>
            </tableColumn>
            <tableColumn id="3" uniqueName="Date" name="Date">
                <xmlColumnPr mapId="1" xpath="/expense-report/expense-item/Date"
    xmlDataType="date"/>
            </tableColumn>
            <tableColumn id="4" uniqueName="expense" name="expense">
                <xmlColumnPr mapId="1" xpath="/expense-report/expense-item/expense"
    xmlDataType="double"/>
            </tableColumn>
            <tableColumn id="5" uniqueName="description" name="description">
                <xmlColumnPr mapId="1" xpath="/expense-report/expense-
    item/description" xmlDataType="string"/>
            </tableColumn>
            <tableColumn id="6" uniqueName="misctype" name="misctype">
                <xmlColumnPr mapId="1" xpath="/expense-report/expense-
    item/Misc/@misctype" xmlDataType="string"/>
            </tableColumn>
        </tableColumns>
        <tableStyleInfo name="TableStyleMedium7" showFirstColumn="0"
    showLastColumn="0" showRowStripes="1" showColumnStripes="0"/>
    </table>
```

The column in the Table titled "type" is bound to an XML mapping, whose map object Id `@mapId` is "1". The `@xpath` value indicates an xpath expression to which this Table column is associated. In this example the Table column "type" corresponds to `@type`, which is an attribute of the `<expense-item>` collection. The corresponding custom schema definition for `@type` indicates a data type of string. This is stored as an xml column property as well, in `@xmlDataType`. This is used for interpreting the data on import and export, and is also used to format the cells for proper rendering in the range.

The remaining columns have similar properties set and can be understood from the discussion above.

3.15.4.4 Single Cell XML

Contents of tableSingleCells.xml

```
    <singleXmlCells
    xmlns="http://schemas.openxmlformats.org/spreadsheetml/2006/5/main">
        <singleXmlCell id="1" name="Table1" displayName="Table1" r="B3"
    connectionId="1">
            <xmlCellPr id="1" uniqueName="currency">
```

```
            <xmlPr mapId="1" xpath="/expense-report/@currency"
xmlDataType="string"/>
        </xmlCellPr>
    </singleXmlCell>
    <singleXmlCell id="2" name="Table2" displayName="Table2" r="C3"
connectionId="1">
        <xmlCellPr id="1" uniqueName="detailed">
            <xmlPr mapId="1" xpath="/expense-report/@detailed"
xmlDataType="boolean"/>
        </xmlCellPr>
    </singleXmlCell>
    <singleXmlCell id="3" name="Table3" displayName="Table3" r="D3"
connectionId="1">
        <xmlCellPr id="1" uniqueName="total-sum">
            <xmlPr mapId="1" xpath="/expense-report/@total-sum"
xmlDataType="double"/>
        </xmlCellPr>
    </singleXmlCell>
    <singleXmlCell id="4" name="Table4" displayName="Table4" r="B6"
connectionId="1">
        <xmlCellPr id="1" uniqueName="First">
            <xmlPr mapId="1" xpath="/expense-report/Person/First"
xmlDataType="string"/>
        </xmlCellPr>
    </singleXmlCell>
    <singleXmlCell id="5" name="Table5" displayName="Table5" r="C6"
connectionId="1">
        <xmlCellPr id="1" uniqueName="Last">
            <xmlPr mapId="1" xpath="/expense-report/Person/Last"
xmlDataType="string"/>
        </xmlCellPr>
    </singleXmlCell>
    <singleXmlCell id="6" name="Table6" displayName="Table6" r="D6"
connectionId="1">
        <xmlCellPr id="1" uniqueName="Email">
            <xmlPr mapId="1" xpath="/expense-report/Person/Email"
xmlDataType="string"/>
        </xmlCellPr>
    </singleXmlCell>
</singleXmlCells>
```

A single cell which has been mapped to an XML node is expressed in much the same way that an entire table is expressed.

The <singleXmlCell> collection is the top level object, like the Table, which identifies the cell in question.

The <xmlCellPr> collection identifies the name for the only 'column' in this structure, the single cell. In this way it is much like a table column definition and the table column-level properties.

The <xmlPr> collection expresses the xml properties for this cell.

3.16 Formulas

3.16.1 Introduction

A SpreadsheetML *formula* is an equation that performs a calculation that typically involves the values of one or more cells in one or more worksheets.

A formula is an expression that can contain the following: constants (§3.16.2), operators (§3.16.3), cell references (§3.16.4), calls to functions (§3.16.5), and names (§3.16.6).

Consider the formula `PI()*(A2^2)`. In this case,

- `PI()` results in a call to the function `PI`, which returns the value of π.
- The cell reference `A2` returns the value in that cell.
- `2` is a numeric constant.
- The caret (^) operator raises its left operand to the power of its right operand.
- The parentheses, `(` and `)`, are used for grouping.
- The asterisk (*) operator performs multiplication of its two operands.

3.16.2 Constants

A *constant* is a predefined value that is not calculated, and, therefore, does not change. A constant can be any of the following:

- A real number
- The logical values TRUE and FALSE
- A string literal
- An array constant
- An error constant

3.16.3 Operators

An *operator* is a symbol that specifies the type of operation to perform on one or more operands. There are arithmetic, comparison, text, and reference operators.

Operators			
Family	*Operator*	*Description*	*Precedence*

Operators			
Reference operators	:	Binary range operator, which takes two cell reference (§3.16.3) operands, and results in one reference to the cells inclusive of, and between, those references. For example, `SUM(B5:C15)`, which references 11 cells.	highest
	,	Binary union operator, which takes two cell reference (§3.16.3) operands, and results in one reference to all those, possibly non-contiguous, cells. For example, `SUM((B5:B15,D5:D15))`, which references 22 cells, 11 from column B, and 11 from column D. The grouping parentheses are necessary to indicate that the comma is an operator rather than a punctuator separating two arguments.	
	space	Binary intersection operator, which takes two cell reference (§3.16.3) operands, and results in one reference to those, possibly non-contiguous, cells that are common. If the intersection is empty, the result is `#NULL!`. For example, `COUNT((B1:C1) (C1:D1))`, which results in a reference to `C1`, while `COUNT((B1:D1) (B1,D1))` results in a single reference to `B1` and `D1`.	
Arithmetic operators	-	Unary minus	
	%	Percentage (unary postfix), which divides its operand by 100. For example, `10.5%`, which results in `0.105`.	
	^	Exponentiation	
	*	Multiplication	
	/	Division	
	+	Addition	
	-	Subtraction	
Text operator	&	Text concatenation (Each of the two operands is converted to text, if necessary, before concatenation.)	
Comparison operators	=	Equal-to	lowest
	<>	Not-equal-to	
	<	Less-than	
	<=	Less-than or equal-to	
	>	Greater-than	

Operators			
	>=	Greater-than-or-equal-to	

Given that cell E38 contains the value 4, and cell F38 contains the value 2, the formula

```
((-1+E38^2)*3-F38)/2
```

produces the result 21.5.

3.16.4 Cell References

Each set of horizontal cells in a worksheet is a *row*, and each set of vertical cells is a *column*. A cell's row and column combination designates the location of that cell.

A *cell reference* designates one or more cells on the same worksheet. Using references, one can:

- Use data contained in different parts of the same worksheet in a single formula.
- Use the value from a single cell in several formulas.
- Refer to cells on other sheets in the same workbook, and even to other workbooks. (References to cells in other workbooks are called *links*.)

There are two cell reference styles: A1 and R1C1.

- In the A1 reference style, each row has a numeric heading numbered sequentially from the top down, starting at 1. Each column has an alphabetic heading named sequentially from left-to-right, A–Z, then AA–AZ, BA–BZ, …, ZA–ZZ, AAA–AAZ, ABA–ABZ, and so on. Column letters are not case-sensitive.

  A relative reference to a single cell is written as its column letter immediately followed by its row number. A relative reference to a whole row is written as its row number. A relative reference to a whole column is written as its column letter. A reference to a range of two or more cells is written as two single-cell references separated by the binary range operator (:). An absolute A1 reference is made up of a cell's column letter followed by its row number, with each being preceded by a dollar character ($). For example, A2, B34, and B5:D8 are relative A1 references. $A$2, $B$34, and $B$5:$D$8 are absolute A1 references. $A2, B$34, and $B5:D$8 are mixed A1 references.
- In the R1C1 reference style, each row has a numeric heading numbered sequentially from the top down, starting at 1. Each column has a numeric heading numbered sequentially from left-to-right, starting at 1.

  A whole row is referenced by omitting the column, and a whole column is referenced by omitting the row. An absolute row or column reference uses absolute row or column numbers, respectively. A relative row or column reference uses, respectively, row or column offsets from the cell containing the formula, with a negative offset indicating a row to the left or a column above, and a positive offset indicateing a row to the right or a column below. Specifying an offset of zero is equivalent to omitting

that offset and its delimiting brackets. For example, `R[-2]C` refers to the cell two rows up and in the same column, `R[2]C[2]` refers to the cell two rows down and two columns to the right, `R2C2` refers to the cell in the second row and in the second column, `R[-1]` refers to the entire row above the active cell, and `R` refers to the current row.

The R1C1 alternate reference style can only be used at runtime.

3.16.5 Functions

A *function* is a named formula that takes zero or more arguments, performs an operation, and, optionally, returns a result. Some examples of function calls are: `PI(), POWER(A1,B3)`, and `SUM(C6:C10)`.

There are more than 300 predefined functions defined by this Office Open XML specification. User-defined functions are also permitted.

3.16.6 Names

A *name* is an alias for a constant, a cell reference, or a formula. A name in a formula can make it easier to understand the purpose of that formula. For example, the formula `SUM(FirstQuarterSales)` is easier to identify than `SUM(C20:C30)`.

3.16.7 Types and Values

Each *expression* has a type. SpreadsheetML formulas support the following types: array, error, logical, number, and text.

An array value or constant represents a collection of one or more elements, whose values can have any type (i.e., the elements of an array need not all have the same type).

3.16.8 Error values

The evaluation of an expression can result in an error having one of a number of *error value*s. These error values are:

Error Value	Reason for Occurrence
`#DIV/0!`	Intended to indicate when any number, including zero, is divided by zero.
`#N/A`	Intended to indicate when a designated value is not available. For example, Some functions, such as `SUMX2MY2`, perform a series of operations on corresponding elements in two arrays. If those arrays do not have the same number of elements, then for some elements in the longer array, there are no corresponding elements in the shorter one; that is, one or more values in the shorter array are not available. This error value can be produced by calling the function `NA`.
`#NAME?`	Intended to indicate when what looks like a name is used, but no such name has been defined. For example, `XYZ/3`, where `XYZ` is not a defined name. `Total is & A10`, where neither `Total` nor `is` is a defined name. Presumably, `"Total is " & A10` was intended. `SUM(A1C10)`, where the range `A1:C10` was intended.

Error Value	Reason for Occurrence
#NULL!	Intended to indicate when two areas are required to intersect, but do not. For example, In the case of SUM(B1 C1), the space between B1 and C1 is treated as the binary intersection operator, when a comma was intended.
#NUM!	Intended to indicate when an argument to a function has a compatible type, but has a value that is outside the domain over which that function is defined. (This is known as a *domain error*.) For example, Certain calls to ASIN, ATANH, FACT, and SQRT might result in domain errors. Intended to indicate that the result of a function cannot be represented in a value of the specified type, typically due to extreme magnitude. (This is known as a *range error*.) For example, FACT(1000) might result in a range error.
#REF!	Intended to indicate when a cell reference is invalid. For example, If a formula contains a reference to a cell, and then the row or column containing that cell is deleted, a #REF! error results. If a worksheet does not support 20,001 columns, OFFSET(A1,0,20000) will result in a #REF! error.
#VALUE!	Intended to indicate when an incompatible type argument is passed to a function, or an incompatible type operand is used with an operator. For example, In the case of a function argument, a number was expected, but text was provided. In the case of 1+"ABC", the binary addition operator is not defined for text.

3.16.9 Dates and Times

Each unique instant in SpreadsheetML time is represented as a distinct non-negative numeric *serial value*, which is made up of an integer date component and a fractional time component. As dates and times are numeric values, they can take part in arithmetic operations.

Numerous functions take as arguments one or more serial values or strings representing dates and/or times. Functions that care only about the date shall ignore any time information that is provided. Functions that care only about the time shall ignore any date information that is provided.

3.16.9.1 Date Representation

Going forward in time, the date component of a serial value increases by 1 each day.

There are two different bases for serial values:

- In the *1900 date base system*, the lower limit is January 1, 1900, which has serial value 1. The upper-limit is December 31, 9999, which has serial value 2,958,465.
- In the *1904 date base system*, the lower limit is January 1, 1904, which has serial value 0. The upper-limit is December 31, 9999, which has serial value 2,957,003.

As to which date base system an implementation uses by default or whether it allows its users to switch between date base systems, is unspecified.

For the 1900 date base system:

DATEVALUE("01-Jan-1900") results in the serial value 1.0000000…
DATEVALUE("03-Feb-1910") results in the serial value 3687.0000000…
DATEVALUE("01-Feb-2006") results in the serial value 38749.0000000…
DATEVALUE("31-Dec-9999") results in the serial value 2958465.0000000…

For the 1904 date base system:

DATEVALUE("01-Jan-1904") results in the serial value 0.0000000…
DATEVALUE("03-Feb-1910") results in the serial value 2225.0000000…
DATEVALUE("01-Feb-2006") results in the serial value 37287.0000000…
DATEVALUE("31-Dec-9999") results in the serial value 2957003.0000000…

3.16.9.2 Time Representation

The time component of a serial value ranges in value from 0–0.99999999, and represents times from 0:00:00 (12:00:00 AM) to 23:59:59 (11:59:59 P.M.), respectively.

Going forward in time, the time component of a serial value increases by 1/86,400 each second. (As such, the time 12:00 has a serial value time component of 0.5.)

TIMEVALUE("00:00:00") results in the serial value 0.0000000…
TIMEVALUE("00:00:01") results in the serial value 0.0000115…
TIMEVALUE("10:05:54") results in the serial value 0.4207639…
TIMEVALUE("12:00:00") results in the serial value 0.5000000…
TIMEVALUE("23:59:59") results in the serial value 0.9999884…

3.16.9.3 Combined Date and Time Representation

Any date component can be added to any time component to produce a serial value for that date/time combination.

For the 1900 date base system:

DATE(1910,2,3)+TIME(10,5,54) results in the serial value 3687.4207639…
DATE(1900,1,1)+TIME(12,0,0) results in the serial value 1.5000000…
DATE(9999,12,31)+TIME(23,59,59) results in the serial value 2958465.9999884…

For the 1904 date base system:

DATE(1910,2,3)+TIME(10,5,54) results in the serial value 2225.4207639…
DATE(1904,1,1)+TIME(12,0,0) results in the serial value 0.5000000…
DATE(9999,12,31)+TIME(23,59,59) results in the serial value 2957003.9999884…

3.16.10 XML Representation

A formula is represented in a worksheet's XML by an f element that contains the text of the formula, and a v element that contains the text version of the last computed value for that formula. This pair of elements is inside a c element, which is, in turn, is inside a row element. Consider the scalar formula SQRT(C2^2+D2^2), where C2 refers to a cell containing the number 12.5, and D2 refers to a cell containing the number 9.6. The corresponding XML might be as follows:

```
<row r="2" spans="2:4">
  <c r="B2" s="40">
    <f>SQRT(C2^2+D2^2)</f>
    <v>15.761027885261798</v>
  </c>
  <c r="C2" s="0">
    <v>12.5</v>
  </c>
  <c r="D2" s="0">
    <v>9.6</v>
  </c>
</row>
```

In the scalar formula CONCATENATE("The total is ",C7," units"), C7 refers to a cell containing the number 23. The corresponding XML might be as follows:

```
<row r="7" spans="2:4" ht="285">
  <c r="B7" s="4" t="str">
    <f>CONCATENATE("The total is ",C7," units")</f>
    <v>The total is 23 units</v>
  </c>
  <c r="C7" s="0">
    <v>23</v>
  </c>
</row>
```

As the function CONCATENATE returns a string, the value for the cell's t attribute is str.

4. Introduction to PresentationML

This clause is informative.

This clause contains a detailed introduction to the structure of a PresentationML document.

The PresentationML file format can be broken down into the following subjects:

- Presentation
- Slides
- Slide Content
- Animation

There are other schemas—most notably DrawingML—that make up a sizeable chunk of the PresentationML file format. These schemas are addressed separately in §5.

4.1 Basics

4.1.1 Introduction

This subclause provides a high-level overview of the content described in the following schemas: pml-baseTypes.xsd, pml-presentation.xsd, pml-presentationProperties.xsd, and pml-viewProperties.xsd.

The PresentationML file format can be broken down into the following subjects:

- Presentation
- Slides
- Slide Content
- Animation

The best way to understand the content in each of these subjects is to cover them in that particular order.

The eight schemas that collectively represent the PresentationML file format can be grouped by subject as follows:

Presentation	Slide	Slide content	Animation
pml-baseTypes.xsd	pml-slide.xsd	pml-embedding.xsd	pml-animationInfo.xsd
pml-presentation.xsd		pml-comments.xsd	
pml-presentationProperties.xsd			
pml-viewProperties.xsd			

There are other schemas—most notably DrawingML—that make up a sizeable chunk of the PresentationML file format. These schemas are addressed separately.

This subclause introduces the first subject, “Presentation”. Other subclauses build on this foundation.

4.1.2 Basic Utilities

The schema pml-baseTypes.xsd contains a set of complex types and simple types that are used by other schemas. The types, or utilities, are used in a variety of cases. Their single implementation provides for rapid and less error-prone changes throughout an implementation.

To provide some insight into the type of information that is being repurposed, here is a sample of these utilities:

- Empty Element
- Name
- Direction
- Index and Index Range
- Slide Show ID
- Slide List Choice
- Slide Relationship
- Customer Data
- Future Extensibility

Each of these is discussed in the following subclauses.

4.1.2.1 Empty Element

Sometimes, the simple presence of an element is sufficient to convey meaning. That is, in some cases, you do not necessarily need information to be a Boolean, an integer, or complex type.

A simple example is the Show Type element group. In this case, a slide show can be one of three types: present, browse, or kiosk. The schema for this element group is as follows:

```
<xsd:group name="EG_ShowType">
  <xsd:choice>
    <xsd:element name="present" type="CT_Empty">
    </xsd:element>
    <xsd:element name="browse" type="CT_ShowInfoBrowse">
    </xsd:element>
    <xsd:element name="kiosk" type="CT_Empty">
    </xsd:element>
  </xsd:choice>
</xsd:group>
```

4.1.2.2 Name

Many constructs within a presentation have names associated with them. In some cases, the names are machine-generated, such as shape names (e.g., rectangle1), while others are user-defined, such as slide shows (e.g., customer-ready).

In one implementation the name simple type is simply an xsd:string. The intent is to restrict this to the appropriate pattern allowed for named constructs. The tentative restriction pattern is:

```
[ \t]*[^ \t].*
```

4.1.2.3 Direction

This multi-purpose simple type is used to convey horizontal versus vertical direction of a variety of types. Such usage can be found in the definition of slide transitions and various shape effects.

4.1.2.4 Index and Index Range

These two utilities are generally used to denote a contiguous set of items within a list. The classic example of usage would be the selection of a set of slides to print.

From a schema-perspective, there is no way to enforce that the start index be equal to or less than the end index.

4.1.2.5 Slide Show ID

This defines the ID for a slide show (also called a custom show). Because slide shows can be named, and that name can change, an implementation needs a method of referring to a slide show that can withstand name changes made by the user. In many cases, for example, with a slide, we can leverage the fact that each slide has a part within the package, in which case we can use the relationship ID. However, since there is no part for each slide show, we are forced to generate an unsigned integer for each slide show and use that.

There is nothing in the schema that prevents two or more slide shows from having the same ID.

4.1.2.6 Slide List Choice

There are many cases in which a user needs to specify a set of slides for an operation. The canonical example is what slides to include in your slide show. Because this operation is frequently required in the file format, one implementation has provided a utility to facilitate this:

```
<xsd:group name="EG_SlideListChoice">
  <xsd:choice>
    <xsd:element name="sldAll" type="CT_Empty" />
    <xsd:element name="sldRg" type="CT_IndexRange" />
    <xsd:element name="custShow" type="CT_CustomShowId" />
  </xsd:choice>
</xsd:group>
```

As the schema above declares, when selecting a set of slides, the user can select all of the slides, a slide range (by declaring a pair of start and end indices) or a particular custom show.

4.1.2.7 Slide Relationship

As described in the Slide Show ID paragraphs above, there are many situations where the format needs to store an ordered list of slides, and does so by storing their slide IDs. This is implemented using two types: a list entry complex type and a list complex type:

```
<xsd:complexType name="CT_SlideRelationshipListEntry">
  <xsd:attribute ref="r:id" use="required"/>
</xsd:complexType>
<xsd:complexType name="CT_SlideRelationshipList">
  <xsd:sequence>
    <xsd:element name="sld" type="CT_SlideRelationshipListEntry"
      minOccurs="0" maxOccurs="unbounded"/>
  </xsd:sequence>
</xsd:complexType>
```

4.1.2.8 Customer Data

There is a set of utilities that facilitate the storage of customer XML data within the file format. Although a topic for a separate paper, essentially, this functionality comes down to the ability to store customer-defined XML in the file format in a way that it can be easily queried, modified and/or surfaced in the presentation. Suffice it to say, the data is stored in a separate part within the package, and hence the utility pairs the object using it with the part within the package.

4.1.2.9 Future Extensibility

There is functionality that provides the ability to extend a subset of objects within the file format for inclusion of additional data over the lifetime of the file format. The utilities provide both the ability to add an alternative representation (e.g., provide a raster image in addition to the XML data for a diagram) as well as additional properties to the objects.

4.1.3 The Presentation Object

The schema pml-presentation.xsd defines the content of the principal or start part for a PresentationML document. This content includes both structural and presentation-level data for the presentation.

Astute readers will quickly identify an apparent duplication of presentation-level data, as there is also a separate schema file, pml-presentationProperties.xsd, which contains presentation-level data. That being said, there is actually no duplication. Rather, the differentiation of what presentation-level data goes into which part is based on two user scenarios: document signatures and document sanitization.

In a document signature scenario, assume a user digitally signs a presentation. There exist two types of data within the presentation package: data which changes the “content” of the presentation and data which is intended to configure an editor or the behavior of an editor. In the first case, any modification to data which

changes the “content” of the presentation must invalidate the signature; in the second case, any modification to that data should not invalidate the signature.

A classic example of this scenario deals with Kinsoku information and the publish path in the HTML settings. If the user changes the Kinsoku information in a file, the file will look (and potentially mean) something different. This is in contrast to a user setting a new HTML publish path for their particular computer.

In a document sanitization scenario, users want to remove all non-necessary information from the file. A typical usage case would be posting a presentation to a company’s Internet site. In this case, you don’t want certain configuration information publicly available. The ideal manner of removal would be to remove an entire part from the presentation package as opposed to editing a part from a package.

Going back to our Kinsoku and HTML publish path example above, the Kinsoku information needs to remain with the file. The HTML publish path could give away internal information about web servers that could be used to facilitate an attack or, more likely, simply provide information about the author to the public (e.g., the path c:\documents and settings\shawnv\webpages strongly implies that “shawnv” published this document).

Going back to the original question—what presentation-level data goes in which part—we see that data that will not invalidate a digital signature or data that should be removed during a sanitization pass should be stored in the part associated with the pml-presentationProperties.xsd schema and other presentation-level data should be stored in the part associated with the pml-presentation.xsd schema.

In addition to structural and presentation-level data defined by this schema, there are also definitions for handling customer data and future extensibility. Again, both of these will be addressed in additional papers.

4.1.3.1 Structural Information

From a structural information perspective, there are two sets of data defined in this schema: core lists and sizes.

The schema first defines a number of lists that serve as the foundation for most objects in the presentation. These lists are as follows:

- Slide IDs
- Slide Masters
- Notes Masters
- Handout Masters
- Custom Shows

It is essential that the reader fully understand the implementation of usage of these lists as they are the foundation for almost all solutions that operate—open, interrogate, modify, write—against the PresentationML file format.

As mentioned above, the lists are defined as a part of list entry and list complex types. The slide master list is defined as follows:

```
<xsd:complexType name="CT_SlideMasterIdListEntry">
  <xsd:attribute ref="r:id" use="required" />
</xsd:complexType>
<xsd:complexType name="CT_SlideMasterIdList">
  <xsd:sequence>
    <xsd:element name="sldMasterId" type="CT_SlideMasterIdListEntry"
        minOccurs="0" maxOccurs="unbounded" />
  </xsd:sequence>
</xsd:complexType>
```

Although not complex or difficult to understand, the lists are called out because they are vital to any solution.

The next pieces of structural information are the sizes for the slides and the notes slides. By storing this information at the presentation level, the implication is that all slides (or all notes slides) in a presentation have the same size. This further implies that all slides in a presentation share the same orientation (i.e., they are all landscape-oriented or all portrait-oriented).

4.1.3.2 Presentation-Level Properties

The presentation-level properties defined in this schema can be grouped into the following groupings:

- Text-Related
- Save-Related
- Editor-Related
- Content-Related

A description for each property within each group follows.

4.1.3.2.1 Text-Related Properties

The first property stores information related to the Kinsoku settings. Kinsoku settings define the list of characters that are not allowed to start or end a line of text for a given East Asian language.

The schema definition of the Kinsoku settings is relatively straightforward: identify the language, the set of invalid start characters, and the set of invalid end characters:

```
<xsd:complexType name="CT_Kinsoku">
  <xsd:attribute name="lang" type="xsd:string" use="optional">
  </xsd:attribute>
  <xsd:attribute name="invalStChars" type="xsd:string" use="required">
  </xsd:attribute>
  <xsd:attribute name="invalEndChars" type="xsd:string" use="required">
  </xsd:attribute>
</xsd:complexType>
```

The second property stores a flag to use strict characters for starting and ending a line of Japanese text. Naturally, this is a simple Boolean attribute:

```
<xsd:attribute name="strictFirstAndLastChars"
  type="xsd:boolean" use="optional" default="true"/>
```

The final text-related property stores information related to any fonts that are embedded in the presentation. To do this, we need to store a list of embedded fonts that reference each part that stores font data (generally, there is a one-font-to-one-part mapping, although this is not a strict rule). This information is defined using three complex types:

```
<xsd:complexType name="CT_EmbeddedFontList">
  <xsd:sequence>
    <xsd:element name="embeddedFont" type="CT_EmbeddedFontListEntry"
        minOccurs="0" maxOccurs="unbounded" />
  </xsd:sequence>
</xsd:complexType>
<xsd:complexType name="CT_EmbeddedFontListEntry">
  <xsd:sequence>
    <xsd:element name="font" type="a:CT_TextFont" minOccurs="1"
      maxOccurs="1" />
    <xsd:element name="regular" type="CT_EmbeddedFontDataId"
      minOccurs="0" maxOccurs="1"/>
    <xsd:element name="bold" type="CT_EmbeddedFontDataId"
      minOccurs="0" maxOccurs="1"/>
    <xsd:element name="italic" type="CT_EmbeddedFontDataId"
      minOccurs="0" maxOccurs="1"/>
    <xsd:element name="boldItalic" type="CT_EmbeddedFontDataId"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
</xsd:complexType>
<xsd:complexType name="CT_EmbeddedFontDataId" >
  <xsd:attribute ref="r:id" use="required"/>
</xsd:complexType>
```

4.1.3.2.2 Save-Related Properties

There is a set of properties that indicate to the editor what should be saved as part of the presentation.

The first such property controls the inclusion of Personally Identifiable Information (“PII”). PII is any information that can be used to identify the author or contributor to a presentation. And while there are cases where this information is exposed visually to the user (e.g., author name in a comment shape), there are other cases where the information is not immediately evident to the user (e.g., the document author name in the list of document properties).

An implementation can provide a mechanism by which the author of a presentation can configure a file to always remove any PII that might otherwise by normally included during a regular save operation. While not a guarantee that no PII is stored in the file (e.g., consider a shape with my name in it—in some cases it describes

content in the file [my position in my group's organization chart] whereas in others it is an editorial directive ["check with ShawnV on this point"]. Given this ambiguity, we cannot solve all cases of this. As a result, this is more a convenience feature than a privacy management feature.

The second set of save-related properties has two groupings of properties. The first controls whether or not fonts will be embedded into the package representing the presentation. The second, enabled by setting the first, allows an implementation to optimize such font embedding to keep the size minimal, at the cost of future editing on other machines.

```
<xsd:attribute name="embedTrueTypeFonts" type="xsd:boolean"
  use="optional" default="false"/>
<xsd:attribute name="saveSubsetFonts" type="xsd:boolean"
  use="optional" default="false"/>
```

The user scenario behind these properties is as follows. Assume you are putting together a presentation to distribute to external customers. You happen to use an East Asian font with an on-disk file size of around 5 megabytes.

Assuming that this font is not a standard font that is widely distributed, not including this font will cause font substitution when the presentation is opened on machines that don't have a copy of the font. In any case, this can radically change the visual appearance of the presentation; in some cases, it can render the presentation unreadable.

Because you cannot afford the presentation to be unreadable or to look unprofessional, you decide to embed the font. By default, the implementation will set embedTrueTypeFonts to true and embed the entire 5 megabyte font file in the presentation package. This will clearly bloat the file, but will ensure that anyone viewing or editing this file will have the same font experience as you originally had (subject to licensing restrictions, of course).

Since you are distributing the presentation, and your primary purpose is for people to view the presentation, you can reduce the amount of font data embedded in the presentation package. By setting the second property (saveSubsetFonts) to true, only those characters in the font that were actually used to create the presentation are saved. This yields less font data stored in the file at the cost of not being able to use unused characters in future edits of the presentation on different machines.

The third property related to saving, controls whether or not an implementation can automatically compress pictures contained in the presentation. This is particularly important given the proliferation of digital cameras and scanners and the increasing importance of small files (e.g., to save network bandwidth, reduce storage required for mail and file servers, etc.).

The final property in this set specifies a password that is required to enable editing of the file using the implementation. Because this is a convenience feature intended to prevent accidental changes to information, it is stored in clear text as an xsd:string.

By storing this information in the file, the implementation will prompt the user for this password in order to open the file read/write; if the user does not provide the correct modify password, the implementation will open the file read-only.

4.1.3.2.3 Editor-Related Properties

The presentation file itself contains data that provide configuration information for the implementation's editor.

For example, the presentation can define a set of smart tags for use while editing the particular presentation. Because Smart Tags are stored in a separate part, the presentation object contains the relationship ID of the Smart Tag part.

In a fully functioning OLE server, PresentationML objects can be embedded into OLE containers, during which time a customer can set a zoom scale. This is stored in the file as a percentage called serverZoom.

An internationalized application might support configuring the editor to respect different screen orientations. For example, in regions of the world where Complex Scripts are in use, it is customary to orient the screen right-to-left. As such, a presentation can request the editor reconfigure itself for such usage scenarios.

Finally, due to changes in the file format and functionality (e.g., graphics and text engines), PresentationML introduces some end-user complexity when working collaboratively with other customers using older versions. To help remedy this, an implementation might support a Compatibility Mode, which restricts the functionality exposed by the editor to optimize the output for the best cross-version collaboration story possible. As a result, each presentation needs to opt-into this mode.

4.1.3.2.4 Content-Related Properties

This set of properties is related to the actual content in the presentation.

End-users can define the starting slide number for numbered slides in each presentation. While it typically starts at one, the user can select any positive number to begin slide numbering. The primary user scenario is when compiling a mega-presentation that is a collection of multiple presentations. A secondary user scenario is when including a presentation in the middle of or at the end of a printed document where you want the slide/page numbers to continue.

Another content-related property controls whether or not header/footer placeholders are to be shown on title slides. In many cases users will use special shapes called header and footer placeholder that contain built-in field codes that control the display of various sorts of information like the date/time and slide number.

In most cases, users like to keep their title slides as simple as possible (much like in the printed world where you want your first page to be clean and streamlined) and hence do not want data like date/times and slide numbers to show up on such slides. This attribute defines this presentation-wide.

The final property relates to creating photo albums. The implementation has a feature that allows the user to generate automatically a presentation based on a set of pictures. During this process, the user can select from a variety of settings, including, but not limited to, what pictures to include, the layout of the pictures on the

slides (e.g., one picture per slide, two pictures per slide, etc.), what type of frame shape to use, etc. All of this information is stored in the presentation for future photo album creation.

4.1.4 Presentation Properties

Those properties that apply to the presentation as a whole, and that are likely to be removed during document sanitization, or are not going to invalidate a digital signature, are defined in pml-presentationProperties.xsd. These properties can be grouped into three primary groupings.

- HTML Publish Properties
- Print Properties
- Slide Show Properties
- View Properties

In addition to this grouping, there are properties that define a Most Recently Used ("MRU") list of colors as well as providing for future extensibility. (The MRU will be discussed in a DrawingML paper and the extensibility will be discussed in a similar paper.)

4.1.4.1 HTML Publish Properties

An implementation must have the ability to save (and publish) a presentation to a web-friendly format like HTML or MHTML. Various parameters are used to configure the application for saving such formats as well as to control what content gets generated. The parameters that configure the application are the HTML Publish properties whereas the content properties are the Web Properties.

The HTML Publish properties provide the author with the ability to control what content gets displayed in the browser when the resulting file—either HTML or MHTML—is viewed using that type of an application. For example, the speaker notes can either be displayed in the frameset or can be hidden from view. This is particularly useful when a speaker's notes are not necessarily in a customer-ready format. It's useful but not necessarily secure.

The author can also specify the title to be displayed in the browser. Although this defaults to the actual file name, or if that is missing, to the content of the first slide's title placeholder, it can be overridden by the author.

Finally the author can specify a publish path to use when saving this file in this format. This is particularly useful for two reasons.

First, because there is a transformation happening, it sometimes takes a few iterations of publishing to get the browser-based experience to be exactly what you want. A classic example of this is the differing animation capabilities between the implementation and certain browsers: it is important to verify that the change in animation behavior continues to work after publishing; if you are not satisfied with the experience, sometimes you need to change the animation in the implementation and republish.

The second reason storing the path is useful is that web server paths can be cumbersome and are often not on the tip of each user's tongue. This allows the user to specify the path once and then publish using the same

location without having to re-specify it. Naturally, being stored in the file format, this allows this data to persist across session.

Indirectly, the HTML Publish properties can prime the Web Properties by defining a target web browser generation (i.e., third, fourth or third and fourth). This is done by setting the appropriate ST_HtmlPublishWebBrowserSupport attribute:

```
<xsd:complexType name="CT_HtmlPublishProperties">
  <xsd:sequence>
    <xsd:group ref="EG_SlideListChoice" minOccurs="1" maxOccurs="1">
    </xsd:group>
  </xsd:sequence>
  <xsd:attribute name="showSpeakerNotes" type="xsd:boolean"
    use="optional" default="true" />
  <xsd:attribute name="pubBrowser"
    type="ST_HtmlPublishWebBrowserSupport"
    use="optional" default="v3v4" />
  <xsd:attribute name="title" type="xsd:string" use="optional"
    default="">
  </xsd:attribute>
    <xsd:attribute ref="r:id" use="required">
  </xsd:attribute>
</xsd:complexType>
```

By providing a target generation, the Web Properties will be set to a predefined package defined for the specified browser generation. Naturally, the user can override the individual Web Property settings.

4.1.4.1.1 Web Properties

As mentioned in the previous subclause, these properties configure the output of the presentation when saved using the HTML or MHTML formats. In this case, a number of parameters can be controlled.

In all multi-slide cases where the presentation is saved using one of these formats, the implementation will create a frameset to bring the various parts of a presentation—the slide content, the speaker notes and the outline—together as well as provide for simple navigation. The color of the HTML frames, the background used and the user interface controls can be controlled to leverage browser settings, use high contrast, etc.

The author can also control how much interactivity will be exposed in the resulting output. For example, the user may elect to disable slide animations and transitions and opt for a more static presentation. Similarly, the author may elect to disable certain scripting features like the ability to resize dynamically the output to match the size of the browser window.

Somewhat related to this is the ability to specify the target screen size which is especially important when targeting the earlier browser generations or user environments where features like JavaScript are disabled.

For an internationalized implementation, there is the ability to control the encoding of text used in the generation of the HTML or MHTML output.

Finally there are a set of parameters that configure the on-disk storage of the resulting output. For example, if the customer knows something about the machine configurations of her audience, she can opt to use better raster graphic formats like PNG that support alpha transparency or elect to include Vector Markup Language ("VML") representations only for vector images.

The customer can also provide some indication as to how the output will be used. If the customer knows that the output will be used like regular files (perhaps passed around on CDs or moved between file shares) the user may elect to store the files in a folder to ensure that a straggling file is not lost; if, however, the target scenario is to put the files on a web server, the user can skip the folder and save the individual files in a flat directory. Similarly, if the customer knows that they are using a web server that only handles "8.3" file names, they can configure the implementation to generate files using names that are "8.3" compliant, as opposed to using long file names that may otherwise cause such web servers problems.

4.1.4.2 Print Options Properties

There is also a set of properties that control the default print behavior for a presentation. The inclusion of this information in the file format simply primes the Print dialog when this presentation is used. It does not force options nor does it represent the last-used set of print options for a presentation.

Using these properties, the author can control the type of output printed. For example, in some cases, authors need to print their slides (one slide per printed page) while in other cases, they want to provide printed handouts for the audience on which to take their own notes (handout pages that can contain anywhere from three to nine slides per printed page, as well as option lines for note taking). In other cases, the author would like to print out notes where each printed page has one slide (anchored at the top) and a text box (anchored at the bottom) with the speaker notes included or simply print the textual outline of the presentation.

The author can also control whether or not hidden slides are included in the printed output, as well as whether or not the output is sent to the printer in color, in grayscale, or in pure black and white.

There is also a set of properties that the author can set that determine if slides are framed on the printed page, if the slides are scaled up to the printed page (e.g., consider non 4x3 aspect ratio slides), etc.

4.1.4.3 Slide Show Properties

This set of presentation-level properties controls the default slide show.

Among the parameters that can be controlled is one that defines the type of slide show. Generally, the classic slide show is characterized by a presenter presenting the presentation to an audience. The presenter controls the flow of the presentation, etc. This is referred to as a "present" slide show. In some cases, however, the presentation is distributed and individuals walk themselves through the slide show. This is referred to as a "browse" slide show. Finally, there are cases where a slide show is prepackaged and used as a kiosk; naturally, it is referred to as a "kiosk" slide show.

Furthermore, the customer can control which slides are to be included in the slide show, what color the pen should be, etc.

Finally, the customer can control various interactivity settings that are to be used for the slide show. This provides the customer the ability to configure their slide show outside the typical settings for a particular slide show type. For example, the user may create a slide show that has a pre-configured animation built with timings (i.e., the time between particular builds or the time between slide transitions), even though she is going to be presenting the content to an audience.

4.1.4.4 View Properties

The schema pml-viewProperties.xsd defines the properties on all of the views found in the implementation.

MS's implementation currently supports the following views:

- Slide View
- Slide Master View
- Notes View
- Handout View
- Notes Master View
- Outline View
- Slide Sorter View

Additionally, the default view, Normal View, is a composite view that pulls from three multiple view property sets.

In general, there is a significant amount of commonality among views. For example, each view contains four common components:

Scale	The zoom scale for the view
Origin	The origin of the view
Variable Scaling	A special zoom scale that configures the application to fit the content of the view into whatever view size is provided
Draft Mode	Controls whether or not a view is in draft mode which is a mode designed to provide the fastest editing/redraw possible by dropping properties like font face, certain colors, pictures, etc.

For those views based on a slide (e.g., slide master view) there are additional common components:

Guide List	Represents the list of drawing guides for this view
Guide Properties	Represents guide properties like direction and position of each guide in the view

Guide List	Represents the list of drawing guides for this view
Guide Settings	Determines if guides should be shown for this view
Snap Settings	Determines if shapes should be snapped to the grid and/or snapped to other shapes for this view

4.2 Slides, Masters, Layouts, and Placeholders

4.2.1 Introduction

This subclause provides a high-level overview of the content described in the pml-slide.xsd schema.

The important aspects of the PresentationML Slides file format are introduced in the following order.

- Masters
- Presentation Slide
- Slide Notes
- Slide Layouts

This subclause provides a structured introduction to the slides portion of the PresentationML file format. Other subclauses build on this foundation and explain more about topics such as animation, comments, and the presentation object.

4.2.2 Masters

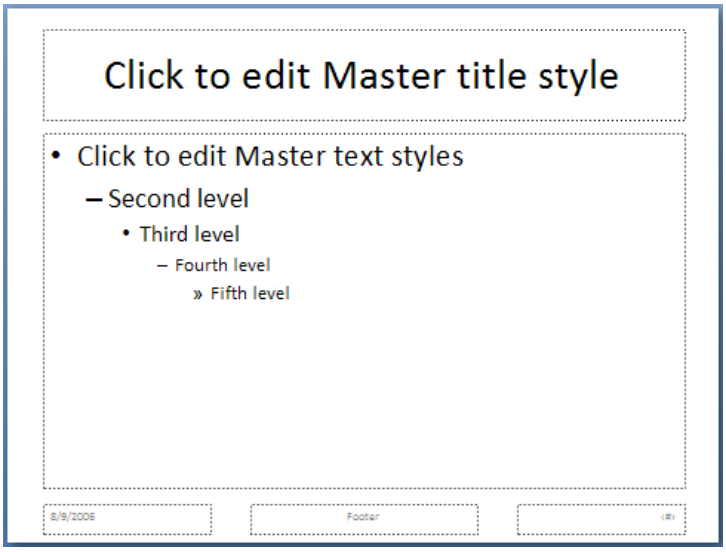
For slides the notion of hierarchy and inheritance applies. A master represents a common layout for the page type in question. For instance, if a slide master had a background set to a gradient fill then all slides referencing to that slide master would have the same background. In addition to setting common attributes of the slides such as background and styling information, the slide master also provides numerous layouts within itself in order to make a presentation that both follows a layout theme and incorporates a high level of variety. The variety is supported through slide layouts which will be discussed in a later section.

4.2.2.1 Slide Master

A *slide master* is a master that is tied specifically to presentation slides. The presentation slides are those that are shown during a presentation. These will be discussed in more detail in a later section on the Presentation Slide. Within a slide master are some common structural elements that should be understood, namely:

- *Common Data* - Common properties that will be inherited by the other slides as well as layout information for presentation slides based on the master slide.
- *Header and Footer* - Header and footer properties for the presentation slides to inherit.
- *Color Map* - Color Mapping for the presentation slides to inherit.
- *Text Styles* - Text Styling information to be used within each placeholder on a presentation slide.
- *Slide Layout List* - A list of slide layouts that provide the variety needed within any presentation. These are applied to a presentation slide which will inherit both the layout of the slide layout in addition to the slide design of the slide master.
- *Timing Information* - Common timing properties used for animation, controls, etc.

- *Transition Information* - Slide transitioning information to be inherited by each presentation slide.

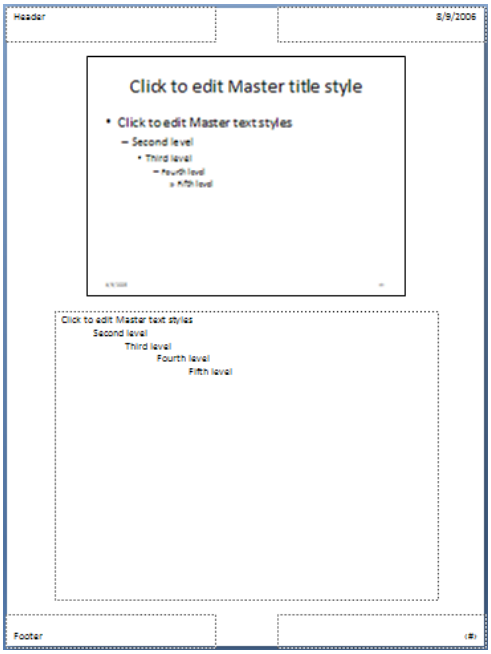


Slides inheriting information from a slide master do have the ability to specify properties that override those specified in the slide master.

4.2.2.2 Notes Master

A *notes master* is a master that specifies properties for slide notes pages. The notes page associated with a presentation slide stores a thumbnail of the presentation slide as well as the presenter's notes about the slide. These will be discussed in more detail in a later section. Within a notes master the important common structural elements are:

- *Common Data* - Common properties that will be inherited by other notes pages as well as the layout information for notes pages based on this master slide. The notes master serves as the pattern for all notes pages.
- *Color Map* - Color Mapping for the notes pages to inherit.

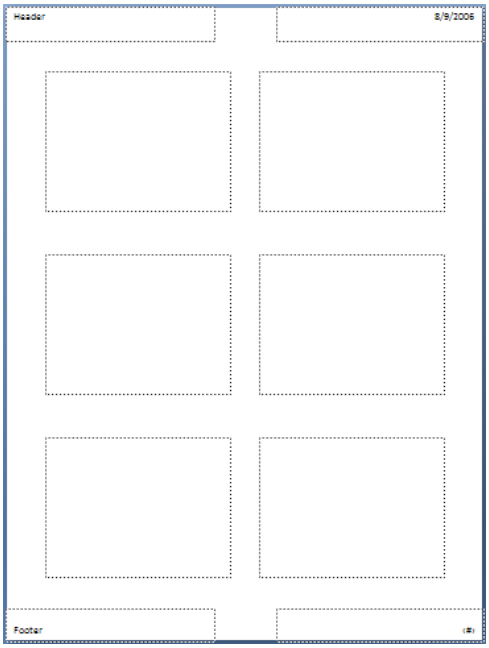


Notes pages inheriting information from a notes master do have the ability to specify properties that override those specified in the notes master.

4.2.2.3 Handout Master

A handout master determines the layout for all handout pages. The handout pages consist of a place to store a thumbnail of each slide with additional elements such as header, footer or graphical information. These will be discussed in more detail in a later section. Within a handout master are some common structural elements that should be understood, namely the following.

- *Common Slide Data* - Common properties and layout information that will be used by all handout pages. The handout master represents how each handout page will look.
- *Header and Footer* - Header and footer properties for all handout pages.
- *Color Map* - Color Mapping for all handout pages.



4.2.3 Presentation Slide

A presentation slide is a slide that inherits slide properties from the corresponding slide master and layout information from the corresponding slide layout. Each presentation slide has the ability to override any of this information that it chooses by specifying local attribute values within the presentation slide. Much like the master slide, the presentation slide contains some common structural elements, namely the following.

- *Common Slide Data* - Common properties and layout information for this presentation slide. Properties listed here that conflict with existing elements specified in the slide master will override those specified in the slide master.
- *Color Map Override* - Color Mapping that will override the inherited color mapping for this presentation slide.
- *Timing Information* - Common timing properties used for animation, controls, etc.
- *Transition Information* - Slide transitioning information for this presentation slide.

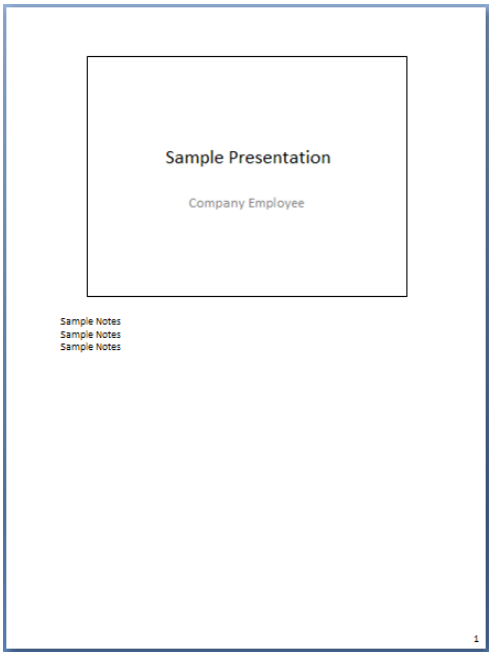
The above list defines the areas that can be used to override inherited components from the master slide and the layout slide. That is, these can be specifically defined on a per-slide basis via the above elements.

4.2.4 Notes Page

A notes page inherits slide properties from the corresponding notes master. The initial layout for a notes page is defined by the single notes master slide. Each notes page has the ability to override any of this information that it chooses by specifying local attribute values within the notes slide. Much like the notes master, the notes page contains some common structural elements, namely the following.

- *Common Slide Data* - Common properties and layout information for this notes page.
- *Color Map Override* - Color Mapping to override the inherited color mapping for this notes page.

The above list defines the areas that can be used to override inherited components from the notes master. That is, these can be specifically defined on a per-slide basis via the above elements.

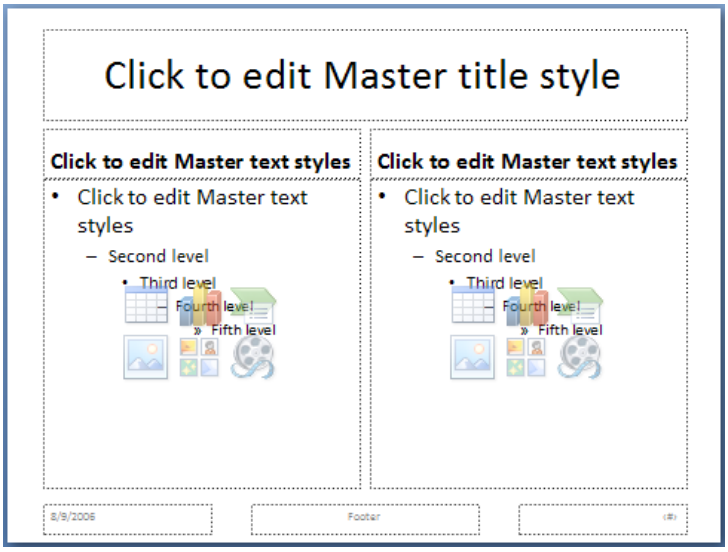


4.2.5 Slide Layouts

A *slide layout* inherits slide properties from the corresponding slide master and sets layout information for all presentation slides that utilize this layout. Each presentation slide has the ability to override any of this information that it chooses by specifying local attribute values within the presentation slide. Much like the slide master, the slide layout contains some common structural elements:

- *Common Slide Data* - Common properties and layout information that will override properties set within the slide master but will be inherited by all presentation slides that utilize this layout.
- *Color Map Override* - Color Mapping that will override the inherited color mapping from the slide master but will be inherited by all presentation slides that utilize this layout.
- *Header and Footer* - Header and footer properties that will override properties set within the slide master but will be inherited by all presentation slides that utilize this layout.
- *Timing Information* - Common timing properties used for animation, controls, etc. These will override properties set within the slide master but will be inherited by all presentation slides that utilize this layout.
- *Transition Information* - Slide transitioning information to be inherited by each presentation slide. These will override properties set within the master slide but will be inherited by all presentation slides that utilize this layout

The above list defines the areas that can be used to override inherited components from the master slide. That is, these can be specifically defined on a per-layout basis via the above elements.



4.3 Comments

4.3.1 Introduction

This document describes the commenting feature for presentations as expressed in PresentationML. The schema that defines this feature is pml-comments.xsd.

Note that it is important to keep in mind that comments are not shapes. The representation of them within the document is left entirely up to the generating application and are thus implementation specific.

4.3.2 Functional Overview

Readers of a presentation can provide feedback to the presentation author in the form of *comments*. Comments can only be applied to slides; they cannot be applied to masters of any type or to notes slides.

At first glance, comments appear to be shapes on the slide surface; however, they are not. Comments differ from regular shapes in two ways:

- Comments cannot be formatted or resized
- The text contained within a comment cannot be formatted

4.3.3 Comment Author List

Presentations contain a list of all authors who have comments in the presentation. This list is commonly referred to as the *Comment Author List* (CAL). The CAL contains one entry for each author. Each entry is made up of five pieces of data: ID, Author Name, Author Initials, Last Index, and Color Index.

Each author that comments on a presentation is assigned an ID, which is a simple integer. This ID is unique within the presentation, and is assigned by the application itself.

The Author Name and Author Initials are taken from the application itself. If no initials are known to the application, the comment author is prompted upon the insertion of the initial comment. Both the Author Name and Author Initials are simple strings; that is, there is no association of the values with an identity (from a security or authentication perspective).

The Last Index (lastIdx) is an integer that documents how many comments the associated author has made in this presentation. When the author makes another comment, that comment is numbered using the next integer, and then this value is updated once again.

The Color Index (clrIdx) is an integer into a color table that is used to provide the solid background fill for the comment shape. The utility that this provides is that all of the comments by a particular author share the same color.

Here is an example of such a CAL:

```
<p:cmAuthorLst>
  <p:cmAuthor id="0" name="Shawn" initials="SV" lastIdx="3" clrIdx="0" />
  <p:cmAuthor id="1" name="Brian" initials="BJ" lastIdx="7" clrIdx="1" />
</p:cmAuthorLst>
```

To determine if an author is already in the CAL, one must consider only the Author Name and Author Initials data. If they both match an entry in the CAL, the author is already considered to be in the CAL; otherwise, the author is considered unique, and a separate entry is added for that author in the CAL.

When the presentation is saved using PresentationML, a separate Comment Authors part is created that contains the CAL.

4.3.4 Comment List

Each slide within a presentation may contain zero or more comments. Each slide with at least one comment starts a list of comments for that slide. Each entry in that list is made up of the following pieces of data:

- Author ID: This represents the ID of the author who created the comment. It matches an entry in the CAL.
- Date/Time: This represents the date and time of the last modification of this particular comment. Although expressed in UTC, its accuracy is dependent on the state of the machine making the edits.
- Index: This is the number assigned to this particular comment, and is one of the comments associated with the specified author. This number should be equal to, or less than, the Last Index value for the author in the CAL. There cannot be duplicate Indexes for the same author.
- Position: This defines the 2D coordinate for the location at which the comment shows up on the slide surface. This is the position of the upper left point of the comment shape.
- The Text data includes all of the text that makes up the body of the comment. Note that this text is expressed differently than other text as expressed in DrawingML. As this text contains no formatting, and is strictly limited to text input, there is no additional data that needs to be stored.

Here is an example of a comment list for a slide:

```
<p:cmLst>
  <p:cm authorId="0" dt="2006-01-30T22:45:13.597" idx="3">
    <p:pos x="10" y="10" />
    <p:text>Need to check with Mary on exact data values</p:text>
  </p:cm>
  <p:cm authorId="1" dt="2006-01-30T22:46:22.082" idx="1">
    <p:pos x="106" y="106" />
    <p:text>This chart is hard to read from afar</p:text>
  </p:cm>
</p:cmLst>
```

When the presentation is saved using PresentationML, a separate Comments part is created for each comment list.

4.4 Animation

4.4.1 Introduction

This subclause provides a high-level overview of the animation settings in PresentationML. This schema is loosely based on the syntax and concepts from the Synchronized Multimedia Integration Language (SMIL), a W3C Recommendation for describing multimedia presentations using XML.

The schema describes all the animations effects on that reside on a slide; it also describes the animation that occurs when going from slide to slide (slide transition).

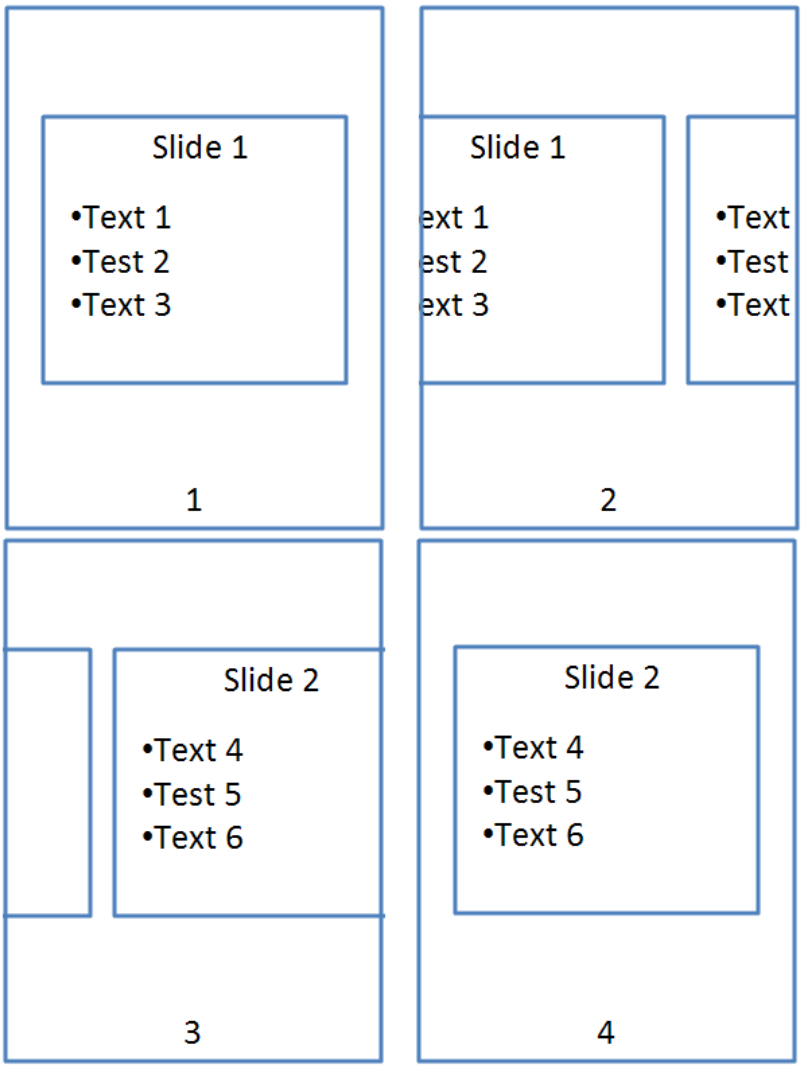
Animations on a slide are inherently time-based and consist of an animation effects on an object or text. However, slide transitions do not follow this concept and always appear before any animation on a slide.

All elements described in this schema are contained within the slide XML file. Superficially, they are in the transition and the timing element as shown below:

```
<p:sld>
  <p:cSld> …
  <p:clrMapOvr> …
  <p:transition> …
  <p:timing> …
</p:sld>
```

4.4.2 Slide Transitions

Slide transitions are the animation effects that displayed in between slides. They are specified in the transition element in the slide XML file. For example, consider a slide with a "push" slide transition as shown below:



The push element should be used as follows:

```
<p:transition>
  <p:push dir="r"/>
</p:transition>
```

4.4.3 Timeline Overview

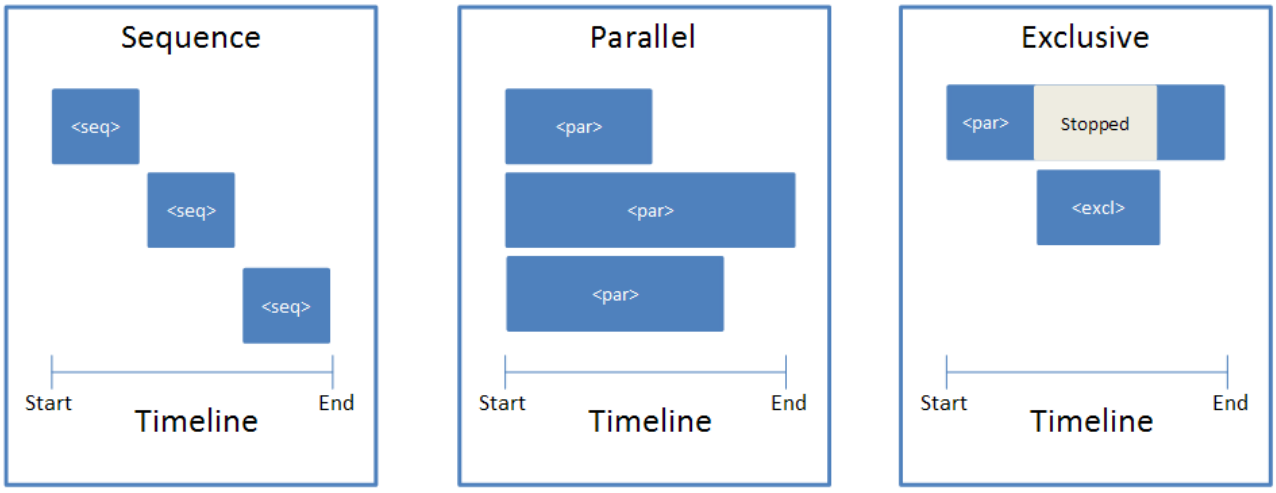
The timeline is an important aspect for animations on a slide. It moderates the amount of time that the animations are run from beginning to end. For example, it allows animation to be started when the slide is loaded or based on an event.

A timeline is composed of timing nodes that dictate at which point a certain animation is shown. A timeline can contain unlimited number of timing nodes; it can also have time nodes nested within them.

There are three types of time nodes:

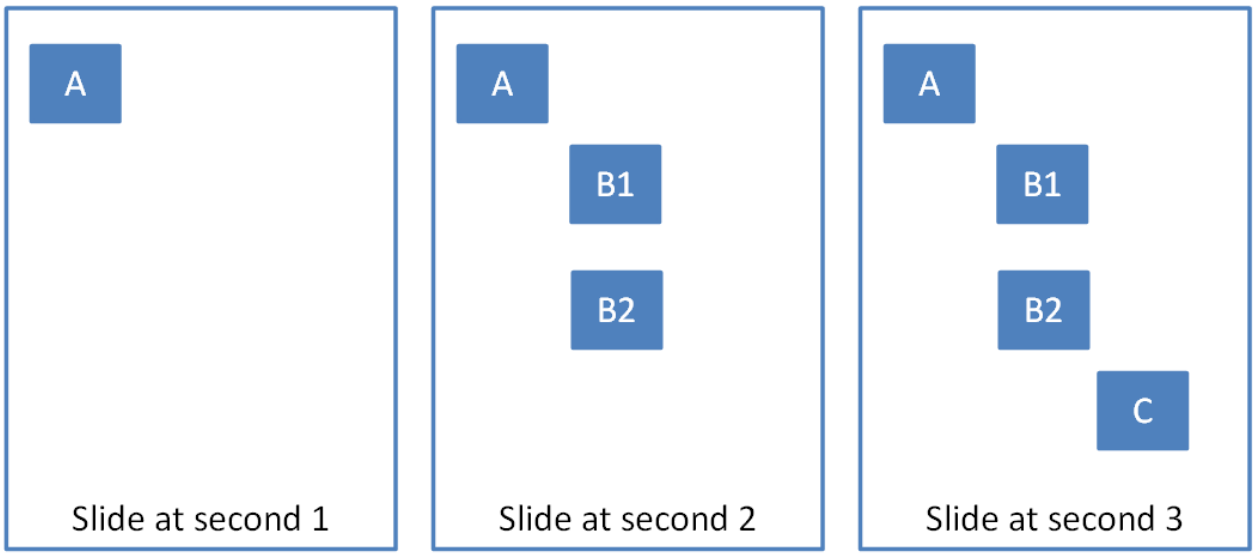
Element	Name	Description
par	Parallel	This is a parallel time node and can be activated along with other parallel time node containers.
seq	Sequence	This is a sequence time node and it can only be activated when the one before it finishes.
excl	Exclusive	This time node is used to pause all other timelines when it is activated.

A conceptual diagram of this is shown below:

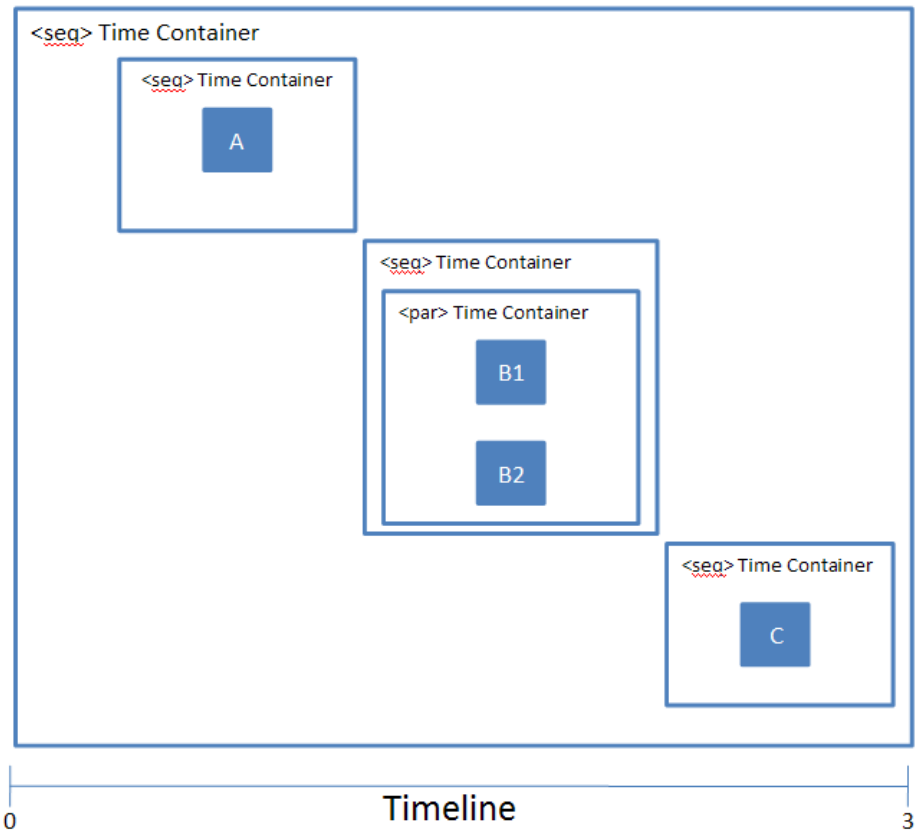


4.4.4 Timeline Construction

To illustrate what the timeline looks like in the slide XML file, suppose we have four rectangles named A, B1, B2, and C that appear on a timeline three seconds long. Rectangle A appears at second 1, B1 and B2 appear together at second 2, and C appears at second 3, as shown below:



The timeline and time containers could look something like:



A typical timeline consists of the following structure:

```
<p:timing>
  <p:tnLst>
    <p:seq concurrent="1" nextAc="seek">
      <p:stCondLst> …
      <p:cTn id="2" dur="indefinite" nodeType="mainSeq">
        <p:childTnLst>
          <p:seq> …   // Square A
          <p:seq>
            <par>….   // Square B1
            <par>….   // Square B2
          </p:seq>
          <p:seq> …   // Square C
        </p:childTnLst>
      </p:cTn>
      <p:prevCondLst> …
      <p:nextCondLst> …
    </seq>
  </p:tnLst>
  <p:bldLst> …
</p:timing>
```

As show, this timeline starts with a timing element that represents the timeline. Within this timeline, there is a child element tnList, which contains a list of time nodes.

In this case, there is one main timing container, which is the seq element. Within this element there are a three of conditional elements, namely stCondList, nextCondList, and prevCondList. These elements contain condition properties that allow for the starting/stopping of the particular time node. This is explained in more detail in §4.4.6.

Following the stCondList element is the cTn element, which describes the properties for this node. Within this element is the childTnList, which contains the nested time nodes that describe the animation sequence mentioned above.

Finally, we have the bldList element, which is used to specify how objects with sub-shapes should be animated. More information can be found in §4.4.7.

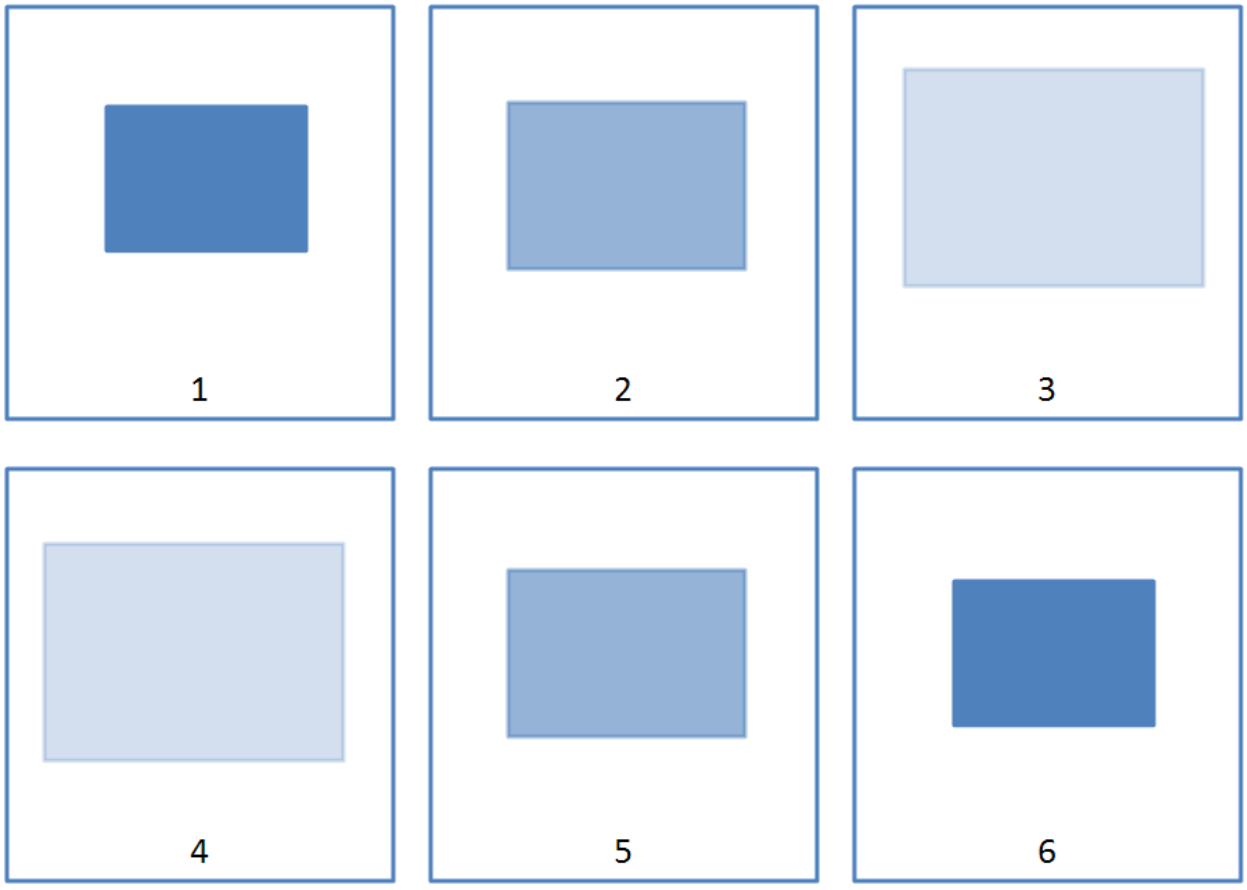
4.4.5 Animation Behaviors

All animation consists of the following basic animation behaviors:

Element	Name	Description
anim	Animate	The animate behavior introduces a generic attribute animation that requires no semantic understanding of the attribute being animated. It can animate numbers.
animColor	Animate Color	This behavior animates the color of a particular element.

Element	Name	Description
animEffect	Animate Effect	This behavior provides the ability to do image transform/filter effects on elements.
animMotion	Animate Motion	Animate motion provides an abstracted way to move positioned elements. It provides the ability to specify from/to/by type motion as well as to use more detailed path descriptions for motion over polylines or bezier curves.
animRotation	Animate Rotation	This behavior allows rotation of an element.
animScale	Animate Scale	Allows animation of the width and/or height of an element over time.

A time node can combine multiple animations for a range of effects. For example, the "flash bulb" animation which scales a shape larger while at the same time having it fade uses two animation behavior elements. An example is shown below:



The representation for this animation effect in the time node element appears like:

```
<p:par>
  <p:cTn id="5">
    <p:stCondLst>….
    <p:childTnLst>
      <p:animEffect transition="out" filter="fade"> …
      <p:animScale>
        <p:cBhvr>
          <p:cTn id="7" dur="500" autoRev="1" fill="hold"/>
          <p:tgtEl>
            <p:spTgt spid="9"/>
          </p:tgtEl>
        </p:cBhvr>
        <p:by x="105000" y="105000"/>
      </p:animScale>
    </p:childTnLst>
  </p:cTn>
</p:par>
```

In this time node, we have two animation effects. One is creating a "fade" effect on the shape using the animEffect element and the other is creating a "scale" effect using the animScale element. All animation behaviors have a cBhvr and cTn element, which stores properties for the animation. For example, we can give the animation behaviors an ID and attributes that set the duration of the animation. The spTgt specifies the target shape to which this animation effect will be applied.

4.4.6 Conditional Properties

Another important aspect of time nodes is conditional properties. There are four such conditions:

Element	Name	Description
stCondLst	Start Condition	Conditions that must be met for a time node to start.
prevCondLst	Previous Condition	Conditions that must be met for a time node to go back to the previous time node.
nextCondLst	Next Conditions	Conditions that must be met for a time node to advance to the next time node.
endCondLst	End Conditions	Conditions that must be met for a time node to end.

Conditional properties are useful for providing finer granularity as to exactly when a time node should be activated. For example, suppose we have a shape with an entrance appearance after five seconds. The stCondLst element should be used as follows:

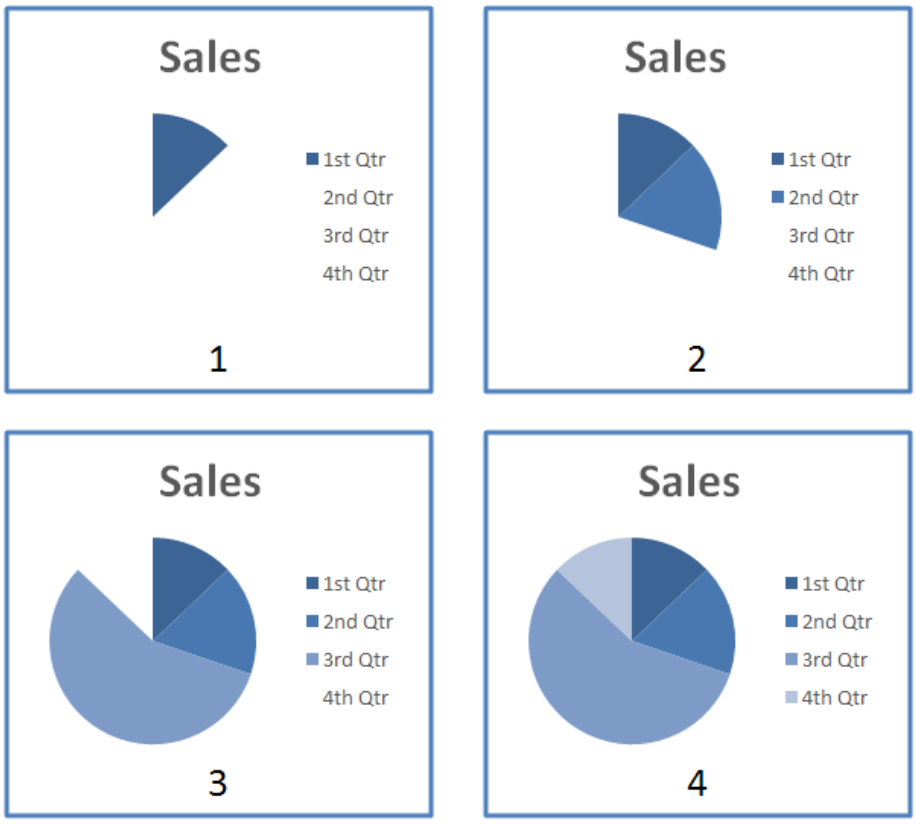
```
<p:par>
  <p:cTn id="5">
    <p:stCondLst>
      <p:cond delay="5000"/>
    </p:stCondLst>
  </p:cTn>
</p:par>
```

4.4.7 Build Animations

Another important aspect of animations is how they are built. This refers to how the different sub-shapes or sub-components of an object are displayed. The different objects that can have build properties are text, diagrams, and charts.

This is specified in the bldLst element.

For example, suppose we want to animate a pie chart, but based on category as shown below:



The representation of this in the slide XML looks like:

```
<p:bldLst>
  <p:bldGraphic spid="4" grpId="0">
    <p:bldSub>
      <a:bldChart bld="category"/>
    </p:bldSub>
  </p:bldGraphic>
</p:bldLst>
```

The bldLst element contains children elements that describe how the different objects should be built. In this case, there is only one graphic to be build, that with id 4. The bldGraphic element contains the bldSub element, which describes how the object should be built. This element then contains the bldChart element with the attribute bld set to `category`.

End of informative text.

4.5 Slide Synchronization

This subclause provides an overview of the p:SldSyncPr element in pml-slideSynchronizationData.xsd.

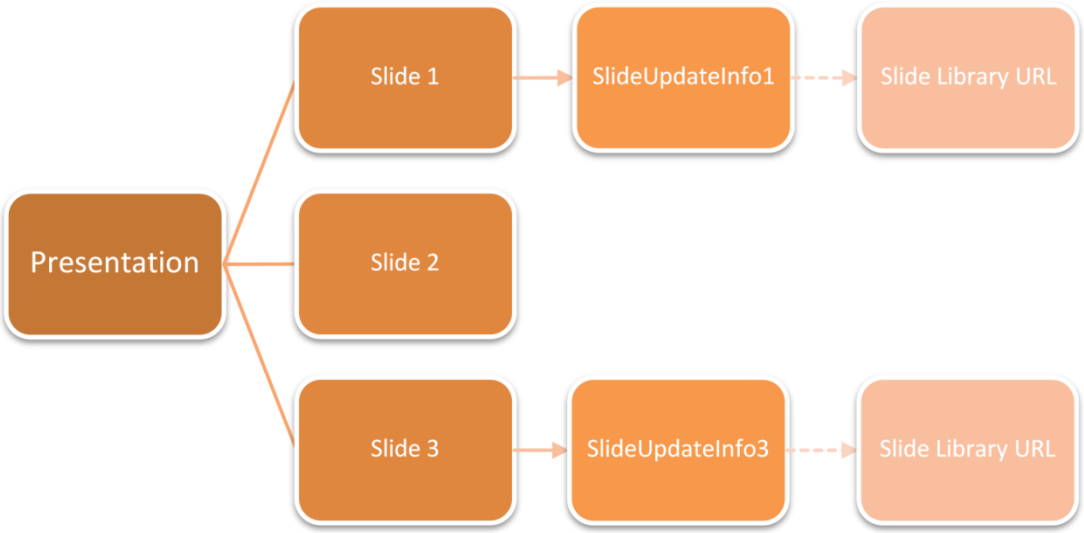
4.5.1 Introduction

A *Slide Library* is a library type in SharePoint Server that exclusively contains single-slide presentations. Users are able to publish and reuse slides to/from these libraries. Furthermore, when a user inserts a slide from the library into a presentation, she is able to create an update relationship so that she is notified when the original slide on the server changes.

It is worth noting that the SlideUpdateInfo part in itself does not define the complete slide update functionality. That part requires a SharePoint Slide Library or compatible server (e.g., a webdav server that emulates SharePoint SOAP methods).

4.5.2 Slide Update Info

For each slide in a presentation that has an update relationship with its counterpart in a Slide Library, a Slide Update Info part is created. The diagram below provides an overview of this relationship.



Each Slide Update Info part is stored under its own folder. For example:

```
/ppt/slideUpdateInfo/slideUpdateInfo1.xml
/ppt/slideUpdateInfo/slideUpdateInfo3.xml
```

The part is indentified for each slide by a relationship with the following characteristics:

```
Type: http://…/slideUpdateInfo
TargetMode: Internal
Target= "<Uri of the slideupdateinfo part for the slide>"
```

The content type of the update info part is application/vnd.openxmlformats-officedocument.presentationml.slideUpdateInfo+xml.

It contains:

- Modified time of the slide on the server when it was inserted (stored in ISO 8061 format).
- Time the slide was inserted into the presentation.
- Regular ID of the slide on the server (saved as a string)

These Slide Update Info parts themselves have an external relationship to the Slide Library Url from which the Slide was inserted.

```
Type: http://.../slidelibraryUrl
TargetMode: External
Target = “<Url of the Slide Library>”
```

Every Slide Update Info part should have exactly one occurrence of this relationship.

Samples:

slideupdateinfo1.xml

```
<p:sldUpdatePr … serverSldId="7991" serverSldModifiedTime="2006-03-08T18:48:33"
  clientInsertedTime="2006-03-10T06:02:33.975" />
```

slideupdateinfo1.xml.rels

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
  <Relationships xmlns="http://.../relationships">
  <Relationship Id="rId1" Type=http://.../slideUpdateUrl
    Target="http://content/slides" TargetMode="External" />
</Relationships>
```

End of informative text.

5. Introduction to DrawingML

This clause is informative.

This clause contains a detailed introduction to the components of DrawingML.

5.1 Basics

5.1.1 Introduction

This subclause provides a high-level overview of the content described in the dml-baseTypes.xsd, dml-compatibility.xsd and dml-lockedCanvas.xsd schemas. The aggregation of the elements within these schemas encompass what has been labeled the DrawingML – Basics sub-clause. That is, the elements contained here are considered to be commonly shared elements among the DrawingML framework.

5.1.2 Overview

This sub-clause is made up of four distinct pieces: Basic Elements, Colors, Compatibility, and Locked Canvas. Together these make up the common elements that are shared across the DrawingML framework. These elements are described below.

5.1.3 Basic Elements

When the common elements of the DrawingML framework are aggregated it can be seen that the most widely used elements are property elements. These reside within every object and allow for the setting of both visual and non-visual object-specific properties. The visual properties are those that affect the appearance of the object when it is rendered on the screen. The non-visual properties on the other hand, do not affect the object's appearance. Instead, these properties are used to store information normally hidden such as identification numbers, human readable names for the objects and specific behaviour that should be obeyed within the UI when manipulating the corresponding object.

5.1.4 Colors

The notion of color plays a vital role in the presentation of DrawingML objects within a document. Virtually all objects are specified to have a corresponding color or set of colors. The notion of color is a common one among graphically-inclined applications. Because of this and the fact that there are many different types of graphic objects available today, we introduce the notion of several different types of color models. The following color models can be used to specify color within a DrawingML based document.

1. RGB – Red, Green, Blue Color Model
2. HSL – Hue, Saturation, Luminance Color Model
3. Scheme – Scheme Based Color Model
4. Preset – Color Presets Color Model

5. System – Operating System Color Model

These different models allow document authors the choice as to which color model would be appropriate for their particular application. Each of these is detailed within the DrawingML Basics reference material.

5.1.5 Compatibility

Compatibility deals with the notion of legacy drawings. Legacy drawings are objects that were supported by previous versions of a generating application, but are no longer provided as an option. In order to store these drawing objects correctly, we introduce the notion of legacy drawing compatibility. This allows for the specification of information used to identify this legacy object and thus allow for full rendering support within current versions of the generating application.

5.1.6 Locked Canvas

Locked Canvas is a minor topic that is similar to compatibility in that it is used to render drawing objects that would otherwise not be recognized due to a lack of information. Locked Canvas, however, goes in the opposite direction from compatibility, and deals with objects that have been created and saved in the current version of a generating application and are being opened in a previous version of the generating application. The locked canvas element acts as a container for more advanced drawing objects. The notion of a locked canvas comes from the fact that the generating application opening the file cannot create this object and thus cannot perform edits either. Thus, the drawing object is locked from all UI adjustments that would normally take place.

5.2 Audio and Video

5.2.1 Introduction

DrawingML contains support for basic audio and video capabilities. The definitions for these structures can be found in dml-audioVideo.xsd.

5.2.2 Functional Overview

Presentation authors can specify that both audio and video can play while a slide is shown in slide show. When such media is inserted into a presentation, a presentation author can specify that the media is to play automatically (that is, in accordance with the slide's animation timeline) or in response to a mouse-click. In either case, media only plays for the duration of time specified, or until the slide changes, whichever is shorter.

Sources for audio content include CD-based files as well as the more traditional disc- or server-based files.

When inserting audio content stored on a CD, the author can specify a start and end track, as well as an index into each track. This information identifies the content from the CD to be played for the specified slide during a slide show.

In cases where the audio or video content is stored on a hard drive or server, the author can only specify the file itself; it will be played in its entirety, or until the slide changes.

5.2.3 DrawingML Syntax

In all three cases, the media objects themselves are stored on the slides using a picture shape. The picture shape uses a blipFill to show the media object on the slide's surface. In both audio cases, the picture used is the icon image, whereas in the video case, the picture used is the poster frame for the video file.

To express this information, the standard blipFill element is used to refer to the image file; and because this refers to a file within the package, a relationship ID is used:

```
<p:pic>
  <p:nvPicPr> …</p:nvPicPr>
  <p:blipFill>
    <a:blip r:embed="rId4" r:link="" />
    <a:stretch>
      <a:fillRect />
    </a:stretch>
  </p:blipFill>
  <p:spPr> … </p:spPr>
</p:pic>
```

As the media objects are related to the slide's timeline—in both the automatic and mouse-click cases—they must have interactivity information stored in the form of a hyperlink.

To express this information, a hyperlink is added to the non-visual shape properties; and because it is a hyperlink, it, too, uses a relationship ID:

```
<p:pic>
  <p:nvPicPr>
    <p:cNvPr id="15" name="Rectangle 15" descr="">
      <a:hlinkClick r:id="rId3" tgtFrame="" tooltip="" />
    </p:cNvPr>
  <p:cNvPicPr />
    <p:nvPr> … </p:nvPr>
  </p:nvPicPr>
  <p:blipFill> … </p:blipFill>
  <p:spPr> … </p:spPr>
</p:pic>
```

The final piece of information required for each media type is the source bits. In both file-based media cases, DrawingML needs to provide a mechanism to specify the location and file name for the media; this is in contrast to the CD-based audio where only track information is required. Regardless of the type of source information required, all of this is stored in application-specific non-visual properties. This is illustrated in the following three XML islands representing each of the three media cases:

CD-Audio	<p:pic> <p:nvPicPr> … <p:cNvPicPr /> <p:nvPr> <a:audioCd> <a:st track="2" time="50" /> <a:end track="3" time="22" /> </a:audioCd> </p:nvPr> … </p:pic>
File-Audio	<p:pic> <p:nvPicPr> … <p:cNvPicPr /> <p:nvPr> <a:audioFile r:embed="" r:link="rId1" /> </p:nvPr> </p:nvPicPr> … </p:pic>
File-Video	<p:pic> <p:nvPicPr> … <p:cNvPicPr /> <p:nvPr> <a:videoFile r:embed="" r:link="rId1" /> </p:nvPr> </p:nvPicPr> … </p:pic>

In the CD-Audio case, there is no capability to choose the particular CD drive that will contain the source. This is a functional limitation.

While the default case is that media is linked, file-based media can also have the source bits included in the package as a separate part. In this case, the relationships point not to an external file but, rather, to a part inside the package.

5.3 Styles

5.3.1 Introduction

This piece of DrawingML deals with the definition of the shared aspects contained within a document theme. The shared-style sheet defines an application-independent set of styling that can be applied to objects within a document and which affects the look of the document and the information and objects it contains. For example, in a presentation, shapes can have a certain look, whereas in an e-mail, all of the text can have certain properties, and headings are styled.

A second topic is the definition of a table style as used within DrawingML. A table style defines the look of a table regardless of the data present in that table.

5.3.2 Shared Style Sheet

The shared-style sheet within DrawingML is responsible for containing different formatting options and style options that can be used within a given document.

5.3.2.1 Theme

The theme is the root-level complex type associated with a shared-style sheet. This complex type holds all of the different formatting options available to a theme, and defines the overall look and feel of a document when themed objects are used within the document. In figure 1 below, we can see an example of two different themes applied to the same slide in a presentation.

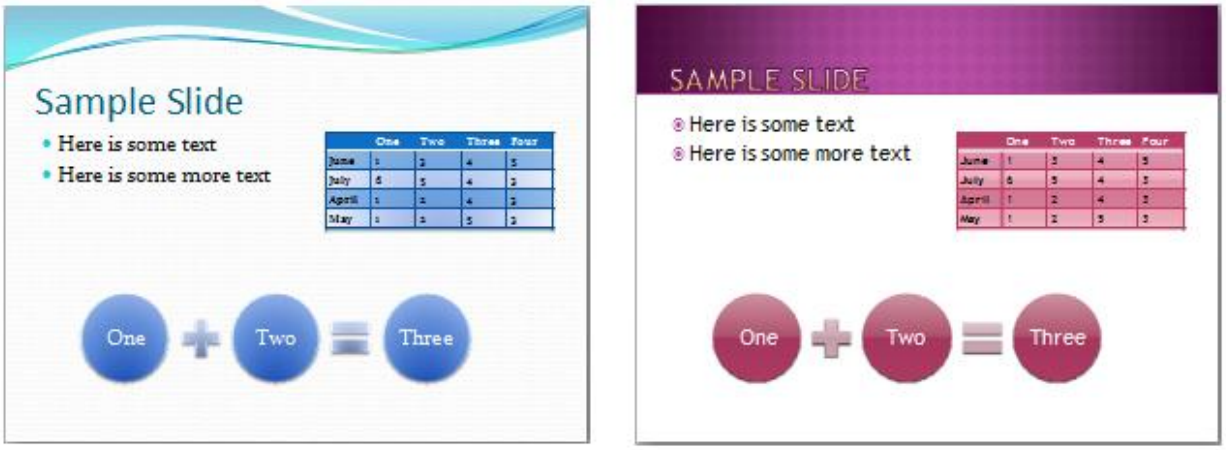


Figure 1: A theme applied to the same slide in a presentation. Not only does the font and colors change, but also the effects applied to the shapes and table.

A theme consists of four main parts, although the themeElements element is the piece that holds the main formatting defined within the theme. The other parts provide overrides, defaults, and additions to the information contained in themeElements. The complex type defining a theme, CT_OfficeStyleSheet, is defined in the following manner:

```
<complexType name="CT_OfficeStyleSheet">
  <sequence>
    <element name="themeElements" type="CT_BaseStyles" minOccurs="1"
      maxOccurs="1"/>
    <element name="objectDefaults" type="CT_ObjectStyleDefaults"
      minOccurs="0" maxOccurs="1"/>
    <element name="extraClrSchemeLst" type="CT_ColorSchemeList"
      minOccurs="0" maxOccurs="1"/>
    <element name="custClrLst" type="CT_CustomColorList" minOccurs="0"
      maxOccurs="1"/>
```

```
      <element name="extLst" type="CT_OfficeArtExtensionList"
        minOccurs="0" maxOccurs="1"/>
    </sequence>
    <attribute name="name" type="xsd:string" use="optional" default=""/>
  </complexType>
```

This complex type also holds a CT_OfficeArtExtensionList, which is used for future extensibility of this complex type.

5.3.2.2 Theme Elements

The complex type CT_BaseStyles defines the theme elements for a theme, and is the workhorse of the theme. The bulk of the shared theme information that is used by a given document is defined here. Within this complex type is defined a color scheme, a font scheme, and a style matrix (format scheme) that defines different formatting options for different pieces of a document. The complex type CT_BaseStyles is defined in the following manner:

```
  <complexType name="CT_BaseStyles">
    <sequence>
      <element name="clrScheme" type="CT_ColorScheme" minOccurs="1"
        maxOccurs="1"/>
      <element name="fontScheme" type="CT_FontScheme" minOccurs="1"
        maxOccurs="1"/>
      <element name="fmtScheme" type="CT_StyleMatrix" minOccurs="1"
        maxOccurs="1"/>
      <element name="extLst" type="CT_OfficeArtExtensionList"
        minOccurs="0" maxOccurs="1"/>
    </sequence>
  </complexType>
```

5.3.2.3 Color Scheme

The complex type CT_ColorScheme defines a set of colors for the theme. The set of colors consists of twelve color slots that can each hold a color of choice. The colors are organized in the following way:

- Dark 1 (dk1) – This represents a dark color, usually defined as a system text color
- Light 1 (lt1) – This represents a light color, usually defined as the system window color
- Dark 2 (dk2) – This represents a second dark color for use
- Light 2 (lt2) – This represents a second light color for use
- Accents 1 through 6 (accent1 through accent6) – These are six colors which can be used as accent colors in the theme
- Hyperlink (hlink) – The color of hyperlinks
- Followed Hyperlink (folHlink) – The color of a followed hyperlink

These colors define the theme colors that objects can utilize within a document. When an object uses a theme color, the color of the object can change when the theme is changed, but will always map to accent 1 if that

were the theme color used by the object. An example of theme colors defined and used can be seen in figure 2.

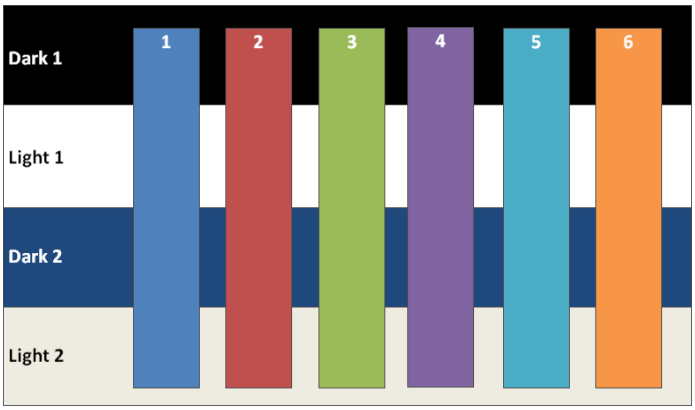

Figure 2: Sample colors defined and used for dark1/2, light1/2, and the six accent colors.

The complex type CT_ColorScheme is defined in the following manner:

```
<complexType name="CT_ColorScheme">
  <sequence>
    <element name="dk1" type="CT_Color" minOccurs="1" maxOccurs="1"/>
    <element name="lt1" type="CT_Color" minOccurs="1" maxOccurs="1"/>
    <element name="dk2" type="CT_Color" minOccurs="1" maxOccurs="1"/>
    <element name="lt2" type="CT_Color" minOccurs="1" maxOccurs="1"/>
    <element name="accent1" type="CT_Color" minOccurs="1"
      maxOccurs="1"/>
    <element name="accent2" type="CT_Color" minOccurs="1"
      maxOccurs="1"/>
    <element name="accent3" type="CT_Color" minOccurs="1"
      maxOccurs="1"/>
    <element name="accent4" type="CT_Color" minOccurs="1"
      maxOccurs="1"/>
    <element name="accent5" type="CT_Color" minOccurs="1"
      maxOccurs="1"/>
    <element name="accent6" type="CT_Color" minOccurs="1"
      maxOccurs="1"/>
    <element name="hlink" type="CT_Color" minOccurs="1" maxOccurs="1"/>
    <element name="folHlink" type="CT_Color" minOccurs="1"
      maxOccurs="1"/>
```

```
      <element name="extLst" type="CT_OfficeArtExtensionList"
        minOccurs="0" maxOccurs="1"/>
    </sequence>
    <attribute name="name" type="xsd:string" use="required"/>
  </complexType>
```

5.3.2.4 Font Scheme

The complex type CT_FontScheme defines a font pair. The pair consists of a major font and a minor font. An example of use would be the major font used in headings for a document and the minor font used for the paragraph parts of a document. The major and minor fonts are defined through a collection of font faces defined on a per-language basis. For example, one may define only a Latin-based font, or one can define many different fonts for different locals for a major or minor font. The font used in the document depends on the user's language.

The complex type CT_FontScheme is defined in the following manner:

```
  <complexType name="CT_FontScheme">
    <sequence>
      <element name="majorFont" type="CT_FontCollection" minOccurs="1"
        maxOccurs="1"/>
      <element name="minorFont" type="CT_FontCollection" minOccurs="1"
        maxOccurs="1"/>
      <element name="extLst" type="CT_OfficeArtExtensionList"
        minOccurs="0" maxOccurs="1"/>
    </sequence>
    <attribute name="name" type="xsd:string" use="required"/>
  </complexType>
```

5.3.2.5 Major and Minor Font (Font Collection)

The complex type CT_FontCollection defines a major and minor font which is used in the font scheme. A font collection consists of a font definition for Latin, East Asian, and complex script. On top of these three definitions, one may also define a font for use in a specific language or languages.

The complex type CT_FontCollection is defined in the following manner:

```
  <complexType name="CT_FontCollection">
    <sequence>
      <element name="latin" type="CT_TextFont" minOccurs="1"
        maxOccurs="1"/>
      <element name="ea" type="CT_TextFont" minOccurs="1" maxOccurs="1"/>
      <element name="cs" type="CT_TextFont" minOccurs="1" maxOccurs="1"/>
      <element name="font" type="CT_SupplementalFont" minOccurs="0"
        maxOccurs="unbounded"/>
```

```
      <element name="extLst" type="CT_OfficeArtExtensionList"
        minOccurs="0" maxOccurs="1"/>
    </sequence>
  </complexType>
```

5.3.2.6 Supplemental Font

The complex type CT_SupplementalFont defines an additional font that is used for language specific fonts in themes. For example, one can specify a font that gets used only within the Japanese language context.

The complex type CT_SupplementalFont is defined in the following manner:

```
  <complexType name="CT_SupplementalFont">
    <attribute name="script" type="xsd:string" use="required"/>
    <attribute name="typeface" type="ST_TextTypeface" use="required"/>
  </complexType>
```

5.3.2.7 Format Scheme (Style Matrix)

The complex type CT_StyleMatrix defines a set of formatting options, which can be referenced by documents that apply a certain style to a given part of an object. For example, in a given shape, say a rectangle, one can reference a themed line style, themed effect, and themed fill that would be theme specific and change when the theme is changed. All of these formatting options are defined within this style matrix. Background fills can also be contained within the style matrix. This is most useful to presentations (but not unique to presentations) which reference different background fills as slide backgrounds. Three sets of each type of formatting are defined, corresponding to subtle, moderate, and intense versions of each style. Combinations of styles are used to create, for example a shape style. An example of this would be a shape style utilizing a subtle fill, moderate line, and intense effect to define the overall look of a shape.

The complex type CT_StyleMatrix is defined in the following manner:

```
  <complexType name="CT_StyleMatrix">
    <sequence>
      <element name="fillStyleLst" type="CT_FillStyleList" minOccurs="1"
        maxOccurs="1"/>
      <element name="lnStyleLst" type="CT_LineStyleList" minOccurs="1"
        maxOccurs="1"/>
      <element name="effectStyleLst" type="CT_EffectStyleList"
        minOccurs="1" maxOccurs="1"/>
      <element name="bgFillStyleLst" type="CT_BackgroundFillStyleList"
        minOccurs="1" maxOccurs="1"/>
    </sequence>
    <attribute name="name" type="xsd:string" use="optional" default=""/>
  </complexType>
```

5.3.2.8 Fill Style List

The complex type CT_FillStyleList defines a set of three fill types. Currently, only three fill types are used, corresponding to subtle, moderate, and intense fills, but the number of fills that can be defined is unbounded. An example of three fills that could be present can be seen in figure 3. In this figure, we have a solid blue fill in the subtle slot, a gradient fill in the moderate slot, and an image fill in the intense slot.

Figure 3: Three different fills increasing in relative intensity.

The complex type CT_FillStyleList is defined in the following manner:

```
<complexType name="CT_FillStyleList">
  <sequence>
    <group ref="EG_FillProperties" minOccurs="3" maxOccurs="unbounded"/>
  </sequence>
</complexType>
```

5.3.2.9 Line Style List

The complex type CT_LineStyleList defines a set of three line styles. As with the fill style list, currently only three styles are utilized corresponding to a subtle line, moderate line, and intense line.

The complex type CT_LineStyleList is defined in the following manner:

```
<complexType name="CT_LineStyleList">
  <sequence>
    <element name="ln" type="CT_LineProperties" minOccurs="3"
      maxOccurs="unbounded"/>
  </sequence>
</complexType>
```

5.3.2.10 Effect Style List

The complex type CT_EffectStyleList defines a set of three effect styles. As with the previously mentioned style lists, three styles are currently utilized corresponding to subtle, moderate, and intense effect styles, but the list remains unbounded. In figure 4 we see subtle, moderate, and intense effects applied to a given shape with a blue fill. The subtle effect is, basically, no effect, whereas the moderate effect is a glow surrounding the shape, and the intense effect is a 3-D bevel along with a shadow applied to the shape.

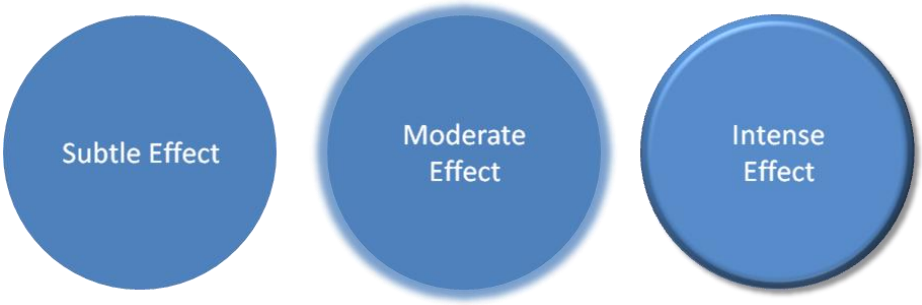

Figure 4: Subtle, moderate, and intense effects applied to a shape that has a blue fill.

The complex type CT_EffectStyleList is defined in the following manner:

```
<complexType name="CT_EffectStyleList">
  <sequence>
    <element name="effectStyle" type="CT_EffectStyleItem" minOccurs="3"
      maxOccurs="unbounded"/>
  </sequence>
</complexType>
```

5.3.2.11 Effect Style Item

The complex type CT_EffectStyleItem holds the properties for a given effect style. Within this complex type, one can define a list of effects (blur, shadow, reflection, etc.) along with any 3-D properties that are to be applied to an object. A basic example of how effects can be applied to a shape can be seen in figure 4.

The complex type CT_EffectStyleItem is defined in the following manner:

```
<complexType name="CT_EffectStyleItem">
  <sequence>
    <group ref="EG_EffectProperties" minOccurs="1" maxOccurs="1"/>
    <element name="scene3d" type="CT_Scene3D" minOccurs="0"
      maxOccurs="1"/>
    <element name="sp3d" type="CT_Shape3D" minOccurs="0" maxOccurs="1"/>
  </sequence>
</complexType>
```

5.3.2.12 Background Fill Style List

The complex type CT_BackgroundFillStyleList defines a set of three fill types similar to the fill style list. Again, they define three fill types corresponding to subtle, moderate, and intense background fills but the list itself is unbounded. The background-fills are meant, for example, to be applied to a slide background, or as the background fill in a shape or table.

The complex type CT_BackgroundFillStyleList is defined in the following manner:

```
<complexType name="CT_BackgroundFillStyleList">
  <sequence>
    <group ref="EG_FillProperties" minOccurs="3" maxOccurs="unbounded"/>
  </sequence>
</complexType>
```

5.3.2.13 Table Styles

Table styles are responsible for the rapid formatting that can be applied to a table. This rapid formatting takes different things into account, such as if the first row or last row should be emphasized, or if there is some type of banding present on the table. All of these different types of formatting can be defined within a table style. An example of different table styles in use on the same table can be seen in figure 1.

Figure 5: Different table styles in use.

The application of a table style to a table formats the table in its entirety. There are numerous complex types that make up a table style. The pieces of a table style will be discussed first, before defining the table style itself.

5.3.2.14 Cell 3D

The complex type CT_Cell3D defines all of the 3-D properties that an individual cell can hold. In the case of a table, these 3-D properties can be a bevel along with a material and a light rig for the cell. More explanation of these three pieces of a CT_Cell3D can be found in the document on 3-D. These properties are applied on a per-cell basis, rather than to the table as a whole. A CT_Cell3D is defined in the following manner:

```
<xsd:complexType name="CT_Cell3D">
  <xsd:sequence>
    <xsd:element name="bevel" type="CT_Bevel" minOccurs="1"
      maxOccurs="1" />
```

```
      <xsd:element name="lightRig" type="CT_LightRig" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="ext" type="CT_OfficeArtExtension" minOccurs="0"
        maxOccurs="1" />
    </xsd:sequence>
    <xsd:attribute name="prstMaterial" type="ST_PresetMaterialType"
      use="optional" default="plastic" />
  </xsd:complexType>
```

This complex type also holds a CT_OfficeArtExtension. This complex type is used for future extensibility and will be seen elsewhere throughout the tables area.

5.3.2.15 Themeable Styles

There are three groups and a complex type that account for style pieces that can be themed. These themed-aspects either pull from the style matrix, or they define an actual fill or effect for example. If they pull their style from the matrix, then an update to the document theme will also update the particular style dynamically. The three groups consist of the following groups:

```
  <xsd:group name="EG_ThemeableFillStyle">
    <xsd:choice>
      <xsd:element name="fill" type="CT_FillProperties" minOccurs="1"
        maxOccurs="1" />
      <xsd:element name="fillRef" type="CT_StyleMatrixReference"
        minOccurs="1" maxOccurs="1" />
    /xsd:choice>
  </xsd:group>
  <xsd:group name="EG_ThemeableEffectStyle">
    <xsd:choice>
      <xsd:element name="effect" type="CT_EffectProperties" minOccurs="1"
        maxOccurs="1" />
      <xsd:element name="effectRef" type="CT_StyleMatrixReference"
        minOccurs="1" maxOccurs="1" />
    </xsd:choice>
  </xsd:group>
  <xsd:group name="EG_ThemeableFontStyles">
    <xsd:choice>
      <xsd:element name="font" type="CT_FontCollection" minOccurs="1"
        maxOccurs="1" />
      <xsd:element name="fontRef" type="CT_FontReference" minOccurs="1"
        maxOccurs="1" />
    </xsd:choice>
  </xsd:group>
```

The three groups above all give a choice between using a themed style, or defining the style themselves. The last type in this group is a complex type used to perform the same task as the above three, only it deals with the lines in the table. The complex type CT_ThemeableLineStyle is defined as:

```
<xsd:complexType name="CT_ThemeableLineStyle">
  <xsd:choice>
    <xsd:element name="ln" type="CT_LineProperties" minOccurs="1"
      maxOccurs="1" />
    <xsd:element name="lnRef" type="CT_StyleMatrixReference"
      minOccurs="1" maxOccurs="1" />
  </xsd:choice>
</xsd:complexType>
```

5.3.2.16 On/Off Property Definition

The simple type ST_OnOffStyleType defines a type with values of on, off, or default. The default value means to follow the parent settings. This comes into play for a themed property, which means follow what the theme says. For an unthemed property, this means to follow the parent setting in the property inheritance chain.

5.3.2.17 Text Properties

The compelex type CT_TableStyleTextStyle defines the table text properties that can be styled. The text properties contain a reference to a themeable font style along with bold and italic being enabled or disabled. The CT_TableStyleTextStyle is defined in the following manner:

```
<xsd:complexType name="CT_TableStyleTextStyle">
  <xsd:sequence>
    <xsd:group ref="EG_ThemeableFontStyles" minOccurs="0"
      maxOccurs="1" />
    <xsd:group ref="EG_ColorChoice" minOccurs="0" maxOccurs="1" />
      <xsd:element name="ext" type="CT_OfficeArtExtension" minOccurs="0"
        maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="b" type="ST_OnOffStyleType" use="optional"
    default="def" />
  <xsd:attribute name="i" type="ST_OnOffStyleType" use="optional"
    default="def" />
</xsd:complexType>
```

5.3.2.18 Cell Border Properties

The complex type CT_TableCellBorderStyle defines the properties of the borders that can be styled in a table. The border styles can be applied to the following different types of borders in a table:

- left – left border
- right – right border
- top – top border

- bottom – bottom border
- insideH – inner horizontal borders
- insideV – inner vertical borders
- tl2br – diagonal border from top left corner to bottom right corner
- tr2bl – diagonal border from top right corner to bottom left corner

The complex type is defined in the following manner:

```
<xsd:complexType name="CT_TableCellBorderStyle">
  <xsd:sequence>
    <xsd:element name="left" type="CT_ThemeableLineStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="right" type="CT_ThemeableLineStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="top" type="CT_ThemeableLineStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="bottom" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="insideH" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="insideV" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="tl2br" type="CT_ThemeableLineStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="tr2bl" type="CT_ThemeableLineStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="ext" type="CT_OfficeArtExtension" minOccurs="0"
      maxOccurs="1" />
  </xsd:sequence>
</xsd:complexType>
```

5.3.2.19 Cell Style Properties

The complex type CT_TableStyleCellStyle contains the definition for cell properties which can be styled. Within this complex type are held the border style, cell fill style, and the cell 3-D. The complex type is defined in the following manner:

```
<xsd:complexType name="CT_TableStyleCellStyle">
  <xsd:sequence>
    <xsd:element name="tcBdr" type="CT_TableCellBorderStyle"
      minOccurs="0" maxOccurs="1" />
```

```
      <xsd:group ref="EG_ThemeableFillStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="cell3D" type="CT_Cell3D" minOccurs="0"
        maxOccurs="1" />
    </xsd:sequence>
  </xsd:complexType>
```

5.3.2.20 Table Background Style

The complex type CT_TableBackgroundStyle defines the style elements associated with the background of the table. The table background style can contain a fill and effect. The complex type is defined in the following manner:

```
  <xsd:complexType name="CT_TableBackgroundStyle">
    <xsd:sequence>
      <xsd:group ref="EG_ThemeableFillStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:group ref="EG_ThemeableEffectStyle" minOccurs="0"
        maxOccurs="1" />
    </xsd:sequence>
  </xsd:complexType>
```

5.3.2.21 Table Part Style

The complex type CT_TablePartStyle defines a structure for holding the style information for a single part of the table. The table is broken up in 13 different parts, which are explained in the next subclause of this document. A table part contains a text style and a cell style and is defined in the following manner:

```
  <xsd:complexType name="CT_TablePartStyle">
    <xsd:sequence>
      <xsd:element name="tcTxStyle" type="CT_TableStyleTextStyle"
        minOccurs="0" maxOccurs="1" />
      <xsd:element name="tcStyle" type="CT_TableStyleCellStyle"
        minOccurs="0" maxOccurs="1" />
    </xsd:sequence>
  </xsd:complexType>
```

5.3.2.22 Table Style

The complex type CT_TableStyle defines the actual table style. Apart from the table background, 13 different parts that can be defined in a table style. These parts work together to define the styling for a table, given the 6 combinations of on/off states for the first row, first column, last row, last column, row banding, and column banding options. The different parts of a table that make up a table style are:

- tableBg – table background (this is not a CT_TablePartStyle)
- wholeTable – formatting for the entire table

- band1Horizontal – applied when row banding is enabled, this is the first row style, which alternates with band2Horiztonal
- band2Horizontal – applied when row banding is enabled, this is the second row style, which alternates with band1Horizontal
- band1Vertical – applied when column banding is enabled, this is the first column style, which alternates with band2Vertial
- band2Vertical – applied when column banding is enabled, this is the second column style, which alternates with band1Vertical
- lastCol – formatting applied to the last column when last column formatting is enabled
- firstCol – formatting applied to the first column when first column formatting is enabled
- lastRow – formatting applied to the last row when last row formatting is enabled
- firstRow – formatting applied to the first row when first row formatting is enabled
- seCell – formatting applied to the cell in the southeast corner of the table when last column and last row are enabled
- swCell – formatting applied to the cell in the southwest corner of the table when first column and last row are enabled
- neCell – formatting applied to the cell in the northeast corner of the table when the last column and first row are enabled
- nwCell – formatting applied to the cell in the northwest corner of the table when the first column and first row are enabled

The table style is defined in the following manner:

```
  <xsd:complexType name="CT_TableStyle">
    <xsd:sequence>
      <xsd:element name="tblBg" type="CT_TableBackgroundStyle"
        minOccurs="0" maxOccurs="1" />
      <xsd:element name="wholeTbl" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="band1H" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="band2H" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="band1V" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="band2V" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="lastCol" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="firstCol" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="lastRow" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
```

```
      <xsd:element name="seCell" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="swCell" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="firstRow" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="neCell" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="nwCell" type="CT_TablePartStyle" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="ext" type="CT_OfficeArtExtension" minOccurs="0"
        maxOccurs="1" />
    </xsd:sequence>
    <xsd:attribute name="styleId" type="ST_Guid" use="required" />
    <xsd:attribute name="styleName" type="xsd:string" use="required" />"
  </xsd:complexType>
```

Also contained within the table style are an ID and a name. The name shows up as the name for the table style, and the ID is the unique id (GUID) that is associated with the table style.

5.3.2.23 Table Style List

The final complex type dealing with table styles is simply a list of table styles. Also contained in this list is the default style which gets applied to the table when the a default is to be used. The complex type CT_TableStyleList is defined in the following manner:

```
  <xsd:complexType name="CT_TableStyleList">
    <xsd:sequence>
      <xsd:element name="tblStyle" type="CT_TableStyle" minOccurs="0"
        maxOccurs="unbounded" />
    </xsd:sequence>
    <xsd:attribute name="def" type="ST_Guid" use="required" />
  </xsd:complexType>
```

5.4 Text

5.4.1 Introduction

This subclause provides a high-level overview of the content described in the following schemas: dml-text.xsd, dml-textParagraph.xsd, dml-textRun.xsd, dml-textCharacter.xsd and dml-textBullet.xsd.

The best way to understand these schemas as they relate to one another is to learn about the DrawingML Text file format in the following order.

- Text Overview
- Body Level Properties

- Paragraph Level Properties
- Run and Character Level Properties

Companion schemas build on the ones discussed in this document. As these are encountered below, pointers to them are provided.

This subclause provides a structured breakdown of the text portion of the DrawingML file format. Other subclauses build on this foundation and explain more about topics such as text frame, text styles, text fields, and embedded fonts.

Note that DrawingML Text described within this document is distinct from WordprocessingML Text in that the file framework surrounding it has been optimized for use in a graphics-centric, presentation-like manner. As a contrast, WordprocessingML Text allows for text to be stored in a format that is optimized for layout of printed documents but not for art-based text as is found within the <a:> namespace.

Note that the use of the "p" namespace within this document references to the PresentationML-specific schemas while the use of the "a" namespace within this document references to the DrawingML-specific schemas.

5.4.2 Overview

Consider an XML tree that has the following basic structure:

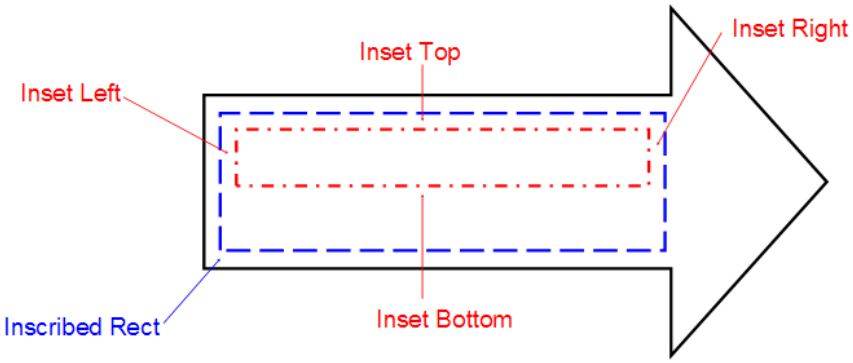
```
<p:sld>
  <p:cSld>
    <p:spTree>
      <p:sp>
        <p:txBody>
          Your text here!
   (not really, there are other elements needed within here)
        </p:txBody>
      </p:sp>
      <p:sp>
      </p:sp>
      …
    </p:spTree>
  </p:cSld>
</p:sld>
```

In the structure above, we are interested in the content contained within the matching p:txBody tags. The understanding of this tag in relation to the basic slide structure above encompasses the schema background needed to digest effectively the remainder of this description.

Note that shapes are the standard container within which all text resides. Usually, the shape does not have any visual properties attached to it and thus no visible shape is rendered; nonetheless, a shape is still present and does house any content text.

Each shape contains an inset rectangle that houses any text attached to that shape. The shape has margins or *insets* that buffer this rectangle on all four sides (top, bottom, left, and right) just like margins on a page. When thinking about text within a shape, it is useful to keep these inset properties in mind.

An illustration of this is provided below.



Let's look at the different element tags contained within p:txBody. Listed below are only those tags discussed here. (Note that this sample framework is a skeleton and does not fully show all elements and attributes needed.)

```
<p:txBody>
  <a:bodyPr />          required, only listed once.
  <a:lstStyle />        optional, if present only listed once.
  <a:p>                 required, no limit on the number of instances.
    <a:pPr />           optional, if present only listed once.
    <a:r>               required, no limit on the number of instances.
      <a:rPr />         optional, if present only listed once.
      <a:t>Your text here!</a:t>
                        Actual text for this run is contained here.
    </a:r>
    <a:endParaRPr />    optional, if present only listed once.
  </a:p>
</p:txBody>
```

Element	Purpose	Description
a:bodyPr	Body Properties	Describes text anchor points, shape autofit, number of columns, text warping, and 3D scenes and lighting effects. See §5.4.3.
a:lstStyle	List Style	Used to define style properties for the paragraph and its nine list levels.

a:p	Single Paragraph	Houses a single paragraph and its corresponding paragraph-level properties. Contained within here are also all the text runs that comprise this paragraph. See §5.4.3.4.
a:pPr	Paragraph Properties	Describes the format and style with which the corresponding paragraph is presented. Some possible settings that can be utilized within this space include, but are not limited to, the following: spacing, margins, and alignment. See §5.4.3.4.
a:r	Single Run	Specifies the existence of a run of text within a paragraph. A run represents the most granular form of text that can be represented in the file format. See §5.4.3.8.
a:rPr	Run Properties	Allows the attachment of properties to the run of text specified by its parent a:r element. These properties include, but are not limited to, the following: underline, strikethrough, and text caps. See §5.4.3.8.
a:t	Actual text	Allows for the storage of the specific text that all these body, paragraph and run level properties are describing. This tag is the most important as it gives context to all the other elements and attributes that have come before it.
a:endParaRPr	Persistent Run Properties	Specifies the properties that are to persist should the user begin to type additional text after this paragraph. This property should only be set when the style that should follow this paragraph is different from the paragraph itself.

5.4.3 Body Level Properties

Schemas represented here: dml-text.xsd

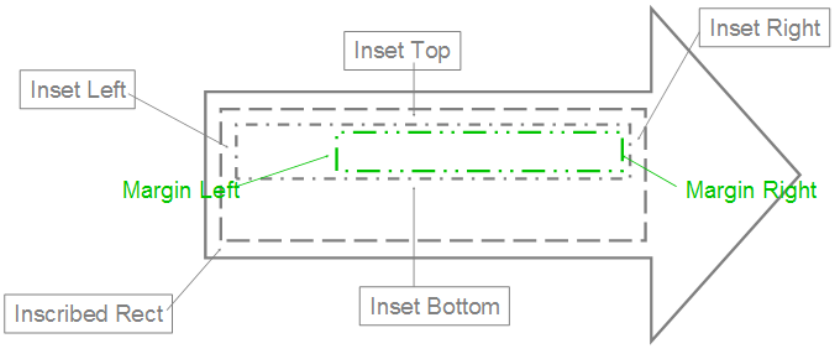
In this subclause, we'll explore the sorts of properties that can be attached to the body as a whole. As shown in the sample XML above, there are three essential property levels available. The body-level properties are to the broadest of these. Note that some of these body-level properties are applied as attributes to the body property tag while others are expressed as child elements. The specific method by which each property is applied can be found in the schemas listed above.

```
<p:txBody>
  <a:bodyPr /> ← Main element covered in this subclause
  <a:lstStyle />
  <a:p>
    <a:pPr />
    <a:r>
      <a:rPr />
      <a:t>Your text here!</a:t>
    </a:r>
  </a:p>
</p:txBody>
```

5.4.3.1 Setting Up the Text Area

Let's start with how a text area might be initially described. This area is the container within which all the child text for this body resides. First, it is useful to understand the inset properties; specifically, the top, bottom, left and right inset properties that are also known as internal margins for the text body. The anchor attribute allows us to specify where the text area should be anchored within its bounding rectangle.

An illustration of this bounding rectangle is highlighted below by the inner green box. Notice here that the bounding rectangle is anchored to the right.



Here's how the text will appear inside. Attribute AutoFit allows for three basic scenarios:

- No AutoFit: The text is allowed to flow outside the container.
- Normal AutoFit: The text is resized using defined constraints to fit inside the container area. (This is used when the text is too large or long to fit in the text container.)
- Shape AutoFit: The actual text container is resized to contain all the text. (This is the only option that can cause the container to have its dimensions changed.)

The term *flow* is used to describe the way in which text moves around inside this text area, and to describe how each of the body properties affects the text within the text area.

One way that text can flow is from one line to the next. This can be done automatically by using the text-wrapping attribute. Another way is to use columns. The XML framework allows for the specification of a

number of columns into which the text is to be automatically broken. This feature also allows for the specifying of the spacing of columns and a right-to-left layout instead of the default left-to-right. Another way that text can flow is vertical instead of horizontal. For this, there are many different types of vertical text that can be described: from text that appears rotated to text where the characters are truly stacked. The text can even be made to flow differently when an East Asian font is specified.

When looking at the flow it is useful to discuss the potential for *overflow*. That is, the text must flow outside the text area because it is too large to fit inside. For this, there are two common types: vertical and horizontal. The vertical overflow can be handled in three ways:

- overflow: This allows the text to flow outside the text area.

- ellipsis: This crops the text that overflows and adds "…" to denote that there is hidden text.

- clip: This crops the text just as ellipsis but does not insert "…", so the user has no indication that there is hidden text.

- Horizontal overflow works exactly like vertical, but with only two options: overflow and clip, which both operate as described above.

5.4.3.2 Manipulating the Text

Let's look at the ways in which the text can be further enhanced at the text body level. Note that the properties that follow apply only to the text body as a whole and thus cannot be applied to a specific paragraph or run within the text body. Theses properties are as follows:

Text Warping: Text within the text area is made to distort itself according to a predefined shape. This shape resides within the bounding box described earlier. This effect is known as *text warping* and has its preset shapes defined further within dml-shapeGeometry.xsd

- 3D Text: Text can be described with respect to a 3D scene. Using this tag provides three basic options:
  - The text resides within a 3D scene, but as planar text.
  - The text is allowed to reside within the 3D scene and has 3D effects (such as bevel or extrusion) applied to it.
  - The text resides on top of a 3D scene. The 3D scene properties are defined dml-shape3DStyles.xsd and dml-shape3DScene.xsd schemas.
- Rotated and Upright Text: A particular rotation can be specified that is applied to the text within the text area. Note that this is different from the rotation that is applied to the shape within which the text area resides. If this attribute is not specifically set then the rotation of the container shape is used.

5.4.3.3 Backwards and Forwards Compatibility

The following areas are of interest when considering support for both past design and future innovation.

- From WordArt: This is specific to dealing with previous WordArt text. Now that text is described as simply a shape, there is no need for a WordArt-specific description. There is, however, the need to identify which pieces of text were from the old WordArt styles in case there is the need to write them back out in their old format.
- Future Extensions: The ability for future extensions has been provided to the body property tag via the ext tag. This can be used the widest way possible as it is a complex type and can thus describe the most complex future properties. Note that each of the schema subclauses below have their own ext tag.

5.4.3.4 Paragraph-Level Properties

Schemas represented here: dml-textParagraph.xsd, dml-textBullet.xsd.

In this subclause, we will explore what sorts of properties can be attached to a paragraph as a whole. Paragraph-level properties allow for a more granular description of the text than the properties of the body tag described earlier. Keep in mind that the properties that can be applied at this level are not duplicates of the body or run levels, but unique only to the paragraph element. Once again, it should be noted that some of these paragraph-level properties are applied as attributes to the paragraph property tag while others are expressed as child elements. The specific method by which each property is applied can be found in the schemas listed above.

```
<p:txBody>
```

```
      <a:bodyPr />
      <a:lstStyle />
      <a:p>
        <a:pPr />  ← Main element covered in this subclause
        <a:r>
          <a:rPr />
          <a:t>Your text here!</a:t>
        </a:r>
      </a:p>
    </p:txBody>
```

5.4.3.5 Spacing, Alignment, and Direction

The XML file format allows for the specifying of spacing both between lines in the form of line spacing, and also outside the paragraph via margins and special before/after spacing. In addition to this, there is also the ability to specify indent spacing for the beginning of the paragraph.

The standard alignment options include left-aligned, right-aligned, centered, justified, and distributed. Justified alignment causes each line of text to be stretched out to a certain point. To ensure that short lines remain readable, they are not stretched. Distributed alignment is quite similar, but stretches every line, regardless of that line's length.

Text direction is specified as either left-to-right (the default) or right-to-left using the specific rtl tag.

5.4.3.6 Tabs and Line Breaks

When the default tabs are not sufficient for the paragraph in question there is the option of including custom tab stops in the XML file format. The information required for this is both a default tab size attribute and a full tab stop list showing all tab stop positions that apply to this paragraph. Keep in mind that if tab stops are not explicitly stated in the file format that the business logic of the application must use its own default positions if tabs are needed.

Line break is a tag that informs the application as to whether it should break up a string of text onto multiple lines based on Latin grammar rules or East Asian grammar rules. The East Asian option uses the Kinsoku settings to determine whether a word is allowed to begin or end a line of text.

5.4.3.7 Adding Bullets

Bullets are specified per paragraph, so bullets can be mixed and matched within a single text body to appear as a coherent text group. The types of bullets available are:

- Character Bullets: Uses a font character to denote a bullet and can be set to appear in any size (percentage of text), color (all available including theme colors), and font. *The properties are Bullet Color, Bullet Size, Bullet Font Typeface, Bullet Character (represents the actual bullet)*

- g Bullet 1
  - g Bullet 2
- g Bullet 3

- Auto-Numbered Bullets: Uses the application logic to assign a series of numbers/characters to a specific bulleted item using just a bullet scheme and a starting number. (When a starting number is used, all bulleted paragraphs listed after the start number are automatically numbered based on this last known start number. The scope of this auto-numbering is only within its current text body, no start at number would ever carry over to a different text body.) The properties are Start At number, Bullet Scheme (letters, roman numerals, etc.), Bullet Color, Bullet Size, and Bullet Font Typeface.
  1. Bullet 1
     1. Bullet 2
  2. Bullet 3

- Blip Bullets: Uses a picture to denote a bulleted item. The only additional property available with this type of applied bullet is the size (percentage of text). If the graphic is not in the applications standard set of graphics then the attached graphic is converted to a PNG format, placed in the document container and is given a relationship id that is used later to reference the image. The properties are Embed id (corresponds to a bullet graphic) and Bullet Size.
  - Bullet 1
    - Bullet 2
  - Bullet 3

5.4.3.8 Run- and Character-Level Properties

Schemas represented here: dml-textRun.xsd, dml-textCharacter.xsd

In this subclause, we'll explore the most granular text properties available in this XML framework, namely those described at the text run and character level. This level is usually the level in which text is broken up into differently formatted parts, because the most commonly used text properties almost all reside at this level. This allows for some very detailed formatting to be represented. Again, it should be noted that for consistency that some of these run and character level properties are applied as attributes to the run property tag while others are expressed as child elements. The specific method by which each property is applied can be found in the schemas listed above.

```
<p:txBody>
  <a:bodyPr />
  <a:lstStyle />
  <a:p>
    <a:pPr />
    <a:r>
      <a:rPr />    ← Main element covered in this subclause
      <a:t>Your text here!</a:t>
    </a:r>
  </a:p>
</p:txBody>
```

5.4.3.9 Visual Properties

When looking to format a run of text the first property that one might need to specify would be the font typeface. The XML file format allows for the specification of not only Latin Fonts but also East Asian, Complex Script, and Symbol fonts as well. These four font buckets give the application additional information that is used to layout text in a manner fitting for the specific font. Along with the actual font being used, comes the size of the font. To specify this simply use the *sz* attribute and along with a value that is 1/100th of the size in points.

Other common formatting properties allowed in the XML framework are bold, italic, underline and strikethrough. The use of both the bold and italic properties is simply via a Boolean value of 0 or 1. The usage of the underline and strikethrough, however, allow a more specific selection to be made. There are 17 values for underline, which range from a single line to wavy double lines. In addition to specifying the style of underline that is to be used, the framework can also specify fill properties for the underline. These are solid color, multi-color gradient, and texture fill. For strikethrough, there are two options: single and double strike through.

When standard formatting isn't adequate, more complex effects can be defined for a specific run of text. The basic breakdown for these is line properties, fill properties and effect properties. Encapsulated within each of these areas is a wide range of customizable effects. A quick look at line properties, for example, reveals the ability to specify a color, gradient, or pattern fill, along with a width and style applied. Along these lines fill properties allows for transparent fill, solid fill, gradient fill, texture fill and even picture fill. While these features alone give the XML file format plenty of robustness in describing text, other features are also available. Because text is treated the same as a shape, a run of text can have virtually all shape effects applied to it just as if it were a shape. These effects include shadow, glow, and reflection, and are placed in an effect list under the run properties tag. An example of what these lines, fills and effects may look like is provided below. More information on these effects can be found in either dml-shapeLineProperties.xsd or dml-shapeEffects.xsd.

```
<a:rPr>
  <a:ln>
    <a:solidFill … />     ← Line properties here
  </a:ln>
  <a:gradFill>
    <a:gsLst … />         ← Fill properties here
  </a:gradFill>
  <a:effectLst>
    <a:reflection … />    ← Effect properties here
  </a:effectLst>
</a:rPr>
```

A few additional properties are worth noting:

- Minimum kerning size: This specifies the smallest font size at which kerning still occurs. When no tag is present for this the default value is 0, allowing kerning at any text size.
- Spacing between characters: The units here are the same as are used for font size. Along the lines of specifying horizontal spacing, vertical spacing can be specified via the baseline tag. This is typically used for subscript and superscript text and is specified in the same units as font size.
- Capitalization and Normalize: Capitalization sets the case of the character to either all small caps or all large caps. For this property there are only these two settings aside from the "none" setting at which point this property is ignored. Normalize height takes all shorter characters and adjusts their height up so that they are the same as taller characters. This property is set via a Boolean value.

5.4.3.10 Properties for Interactivity

Hyperlinks: The XML file format allows for the inputting of hyperlinks that are activated by either click or mouse over. These two tags are HyperlinkClick and HyperlinkMouseOver, respectfully. They both allow for the specifying of a link to another resource very much like those found on a common website.

Spelling and Smart Tags: Although spelling is very much an application-specific part of text editing and is most likely to be done within the application itself there are a few ways that spelling settings and preferences can be persisted within the file format. One way is through the spelling error bit, which simply saves whether there is a known spelling mistake. The next is the spelling dirty bit. This gets set whenever the user has entered new text and the application has not had a chance to check for spelling errors on this piece of text. Lastly, in this realm we actually have a user preference of no proofing that is persisted for the next time a document is opened. This allows the user to specify a word that they do not want to have checked for spelling. Along with spell-checking comes the notion of smart tags which must be checked for just like spelling mistakes. For this there are two related tags. The first is the smart tag clean, which allows for a boolean value to be set determining if this portion of text has been checked for the presence of new smart tags. The next is the actual smart tag id. Once a piece of text has been determined to be a smart tag then a smart tag id is assigned which points to the actual smart tag information.

5.4.3.11 International Language Support

There exists the notion of the language id, which is simply a value that assists the application in laying out the text. The tags that help with this are the language id tag and the alternate language id tag. Together, these allow the file format to be robust and handle multiple languages for a single run of text. In addition, there is also the kumimoji tag, which aids with the layout of East Asian text by specifying whether numbers appear vertically with text (default) or horizontally. An illustration of a run of text with kumimoji applied is provided below.

5.5 Tables

5.5.1 Introduction

This document provides a high-level overview of the content described in the schemas dml-table.xsd and dml-tableStyle.xsd.

This aspect of DrawingML deals with the definition of a table and the associated styling information. The first part describes the table styles aspect, while the second part describes the definition of a table within DrawingML. The above-mentioned schemas fall into the following groupings:

Table Styles	Table Definition
dml-tableStyle.xsd	dml-table.xsd

5.5.2 Table Styles

Table styles are responsible for the rapid formatting that can be applied to a table. This rapid formatting takes different things into account, such as if the first row or last row should be emphasized, or if there is some type of banding present on the table. All of these different types of formatting can be defined within a table style. An example of different table styles in use on the same table can be seen in figure 1.

	Red	Blue	Yellow
1st Qtr	21.5	18.3	4.5
2nd Qtr	17.4	3.6	2.2
3rd Qtr	9.1	19.8	7.9
4th Qtr	12.2	13.4	12.1

	Red	Blue	Yellow
1st Qtr	21.5	18.3	4.5
2nd Qtr	17.4	3.6	2.2
3rd Qtr	9.1	19.8	7.9
4th Qtr	12.2	13.4	12.1

	Red	Blue	Yellow
1st Qtr	21.5	18.3	4.5
2nd Qtr	17.4	3.6	2.2
3rd Qtr	9.1	19.8	7.9
4th Qtr	12.2	13.4	12.1

	Red	Blue	Yellow
1st Qtr	21.5	18.3	4.5
2nd Qtr	17.4	3.6	2.2
3rd Qtr	9.1	19.8	7.9
4th Qtr	12.2	13.4	12.1

Figure 6: Different table styles in use.

The application of a table style to a table formats the table in its entirety. A number of complex types make up a table style. The pieces of a table style are discussed first, before the table style itself is defined.

5.5.2.1 Cell 3-D

The complex type, CT_Cell3D, defines all of the 3-D properties that an individual cell can hold. In the case of a table, these 3-D properties can be a bevel along with a material and a light rig for the cell. (More explanation of these three pieces of a CT_Cell3D can be found in §5.6.) These properties are applied on a per-cell basis, rather than to the table as a whole. A CT_Cell3D is defined in the following manner:

```
<xsd:complexType name="CT_Cell3D">
  <xsd:sequence>
    <xsd:element name="bevel" type="CT_Bevel" minOccurs="1"
      maxOccurs="1" />
    <xsd:element name="lightRig" type="CT_LightRig" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="extLst" type="CT_OfficeArtExtensionList"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="prstMaterial" type="ST_PresetMaterialType"
    use="optional" default="plastic" />
</xsd:complexType>
```

This complex type also holds a CT_OfficeArtExtensionList. This complex type is used for future extensibility and will be seen elsewhere throughout the tables area.

5.5.2.2 Themeable Styles

Three groups and a complex type account for style pieces that can be themed. These themed aspects either pull from the style matrix, or they define an actual fill or effect for example. If they pull their style from the matrix, then an update to the document theme will also update the particular style dynamically. The three groups consist of the following groups:

```
<xsd:group name="EG_ThemeableFillStyle">
  <xsd:choice>
    <xsd:element name="fill" type="CT_FillProperties" minOccurs="1"
      maxOccurs="1" />
    <xsd:element name="fillRef" type="CT_StyleMatrixReference"
      minOccurs="1" maxOccurs="1" />
  </xsd:choice>
</xsd:group>
<xsd:group name="EG_ThemeableEffectStyle">
  <xsd:choice>
    <xsd:element name="effect" type="CT_EffectProperties"
      minOccurs="1" maxOccurs="1" />
    <xsd:element name="effectRef" type="CT_StyleMatrixReference"
      minOccurs="1" maxOccurs="1" />
  </xsd:choice>
</xsd:group>
<xsd:group name="EG_ThemeableFontStyles">
  <xsd:choice>
    <xsd:element name="font" type="CT_FontCollection" minOccurs="1"
      maxOccurs="1" />
    <xsd:element name="fontRef" type="CT_FontReference" minOccurs="1"
      maxOccurs="1" />
  </xsd:choice>
</xsd:group>
```

The three groups above all give a choice between using a themed style or defining the style themselves. The last type in this group is a complex type used to perform the same task as the above three, only it deals with the lines in the table. The complex type, CT_ThemeableLineStyle, is defined as:

```
<xsd:complexType name="CT_ThemeableLineStyle">
  <xsd:choice>
    <xsd:element name="ln" type="CT_LineProperties" minOccurs="1"
      maxOccurs="1" />
    <xsd:element name="lnRef" type="CT_StyleMatrixReference"
      minOccurs="1" maxOccurs="1" />
  </xsd:choice>
</xsd:complexType>
```

5.5.2.3 On/Off Property Definition

The simple type, ST_OnOffStyleType, defines a type with values of on, off, or default. A value of default indicates that parent settings should be used. Thus, for a themed property, default indicates that the theme properties should be followed. For an unthemed property, default means that the parent setting in the property inheritance chain should be followed.

5.5.2.4 Text Properties

The complex type, CT_TableStyleTextStyle, defines the table text properties that can be styled. The text properties contains a reference to a themeable font style along with bold and italic being enabled or disabled. The CT_TableStyleTextStyle is defined in the following manner:

```
<xsd:complexType name="CT_TableStyleTextStyle">
  <xsd:sequence>
    <xsd:group ref="EG_ThemeableFontStyles" minOccurs="0"
      maxOccurs="1" />
    <xsd:group ref="EG_ColorChoice" minOccurs="0" maxOccurs="1" />
      <xsd:element name="extLst" type="CT_OfficeArtExtensionList"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="b" type="ST_OnOffStyleType" use="optional"
    default="def" />
  <xsd:attribute name="i" type="ST_OnOffStyleType" use="optional"
    default="def" />
</xsd:complexType>
```

5.5.2.5 Cell Border Properties

The complex type, CT_TableCellBorderStyle, defines the properties of the borders that can be styled in a table. The border styles can be applied to the following different types of borders in a table:

- `left` – left border
- `right` – right border
- `top` – top border
- `bottom` – bottom border
- `insideH` – inner horizontal borders
- `insideV` – inner vertical borders
- `tl2br` – diagonal border from top left corner to bottom right corner
- `tr2bl` – diagonal border from top right corner to bottom left corner

The complex type is defined in the following manner:

```
<xsd:complexType name="CT_TableCellBorderStyle">
  <xsd:sequence>
    <xsd:element name="left" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="right" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="top" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="bottom" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="insideH" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="insideV" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="tl2br" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="tr2bl" type="CT_ThemeableLineStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="extLst" type="CT_OfficeArtExtensionList"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
</xsd:complexType>
```

5.5.2.6 Cell Style Properties

The complex type, CT_TableStyleCellStyle, contains the definition for cell properties that can be styled. Within this complex type are held the border style, cell fill style, and the cell 3-D. The complex type is defined in the following manner:

```
<xsd:complexType name="CT_TableStyleCellStyle">
  <xsd:sequence>
    <xsd:element name="tcBdr" type="CT_TableCellBorderStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:group ref="EG_ThemeableFillStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="cell3D" type="CT_Cell3D" minOccurs="0"
      maxOccurs="1" />
  </xsd:sequence>
</xsd:complexType>
```

5.5.2.7 Table Background Style

The complex type, CT_TableBackgroundStyle, defines the style elements associated with the background of the table. The table background style can contain a fill and effect. The complex type is defined in the following manner:

```
<xsd:complexType name="CT_TableBackgroundStyle">
  <xsd:sequence>
    <xsd:group ref="EG_ThemeableFillStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:group ref="EG_ThemeableEffectStyle" minOccurs="0"
      maxOccurs="1" />
  </xsd:sequence>
</xsd:complexType>
```

5.5.2.8 Table Part Style

The complex type, CT_TablePartStyle, defines a structure for holding the style information for a single part of the table. The table is broken up in 13 different parts which will be explained in the next subclause of this document. A table part contains a text style and a cell style and is defined in the following manner:

```
<xsd:complexType name="CT_TablePartStyle">
  <xsd:sequence>
    <xsd:element name="tcTxStyle" type="CT_TableStyleTextStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="tcStyle" type="CT_TableStyleCellStyle"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
</xsd:complexType>
```

5.5.2.9 Table Style

The complex type, CT_TableStyle, defines the actual table style. There are thirteen different parts (outside of the table background) that can be defined in a table style. These parts work together to define the styling for a table, given the six combinations of on/off states for the first row, first column, last row, last column, row banding, and column banding options. The different parts of a table that make up a table style are:

- tableBg – table background (this is not a CT_TablePartStyle)
- wholeTable – formatting for the entire table
- band1Horizontal – applied when row banding is enabled, this is the first row style, which alternates with band2Horiztonal
- band2Horizontal – applied when row banding is enabled, this is the second row style, which alternates with band1Horizontal
- band1Vertical – applied when column banding is enabled, this is the first column style, which alternates with band2Vertial
- band2Vertical – applied when column banding is enabled, this is the second column style, which alternates with band1Vertical
- lastCol – formatting applied to the last column when last column formatting is enabled
- firstCol – formatting applied to the first column when first column formatting is enabled
- lastRow – formatting applied to the last row when last row formatting is enabled
- firstRow – formatting applied to the first row when first row formatting is enabled

- seCell – formatting applied to the cell in the southeast corner of the table when last column and last row are enabled
- swCell – formatting applied to the cell in the southwest corner of the table when first column and last row are enabled
- neCell – formatting applied to the cell in the northeast corner of the table when the last column and first row are enabled
- nwCell – formatting applied to the cell in the northwest corner of the table when the first column and first row are enabled

The table style is defined in the following manner:

```
<xsd:complexType name="CT_TableStyle">
  <xsd:sequence>
    <xsd:element name="tblBg" type="CT_TableBackgroundStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="wholeTbl" type="CT_TablePartStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="band1H" type="CT_TablePartStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="band2H" type="CT_TablePartStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="band1V" type="CT_TablePartStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="band2V" type="CT_TablePartStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="lastCol" type="CT_TablePartStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="firstCol" type="CT_TablePartStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="lastRow" type="CT_TablePartStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="seCell" type="CT_TablePartStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="swCell" type="CT_TablePartStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="firstRow" type="CT_TablePartStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="neCell" type="CT_TablePartStyle" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="nwCell" type="CT_TablePartStyle" minOccurs="0"
      maxOccurs="1" />
```

```
      <xsd:element name="extLst" type="CT_OfficeArtExtensionList"
        minOccurs="0" maxOccurs="1" />
    </xsd:sequence>
    <xsd:attribute name="styleId" type="ST_Guid" use="required" />
    <xsd:attribute name="styleName" type="xsd:string" use="required" />
  </xsd:complexType>
```

Also contained within the table style is an ID and a name. The name shows up as the name for the table style and the ID is the unique id (GUID) that is associated with the table style.

5.5.2.10 Table Style List

The final complex type dealing with table styles is simply a list of table styles. Also contained in this list is the default style which is applied to the table when the a default is to be used. The complex type, CT_TableStyleList, is defined in the following manner:

```
  <xsd:complexType name="CT_TableStyleList">
    <xsd:sequence>
      <xsd:element name="tblStyle" type="CT_TableStyle" minOccurs="0"
        maxOccurs="unbounded" />
    </xsd:sequence>
    <xsd:attribute name="def" type="ST_Guid" use="required" />
  </xsd:complexType>
```

5.5.3 Table Definition

In this subclause, the focus is on the actual definition of a table and the data contained within the table. There are not as many complex types in this subclause as with the table style subclause, but they are organized in the same way as the table style section.

5.5.3.1 Cell Properties

The complex type, CT_TableCellProperties, holds all the information that deals with the properties of a given cell. The cell properties contain a section for the different line properties (ln*), the cell fill properties, the 3-D properties, cell margin information (mar*), anchoring information (anchor and anchorCtr), a vertical text type, and finally an attribute which defines the behavior of horizontal text overflow (horzOverflow). As with many other types defined in this document, CT_TableCellProperties contains an element reserved for future extensibility. The complex type is defined in the following manner:

```
  <xsd:complexType name="CT_TableCellProperties">
    <xsd:sequence>
      <xsd:element name="lnL" type="CT_LineProperties" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="lnR" type="CT_LineProperties" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="lnT" type="CT_LineProperties" minOccurs="0"
        maxOccurs="1" />
```

```
      <xsd:element name="lnB" type="CT_LineProperties" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="lnTlToBr" type="CT_LineProperties"
        minOccurs="0" maxOccurs="1" />
      <xsd:element name="lnBlToTr" type="CT_LineProperties"
        minOccurs="0" maxOccurs="1" />
      <xsd:element name="cell3D" type="CT_Cell3D" minOccurs="0"
        maxOccurs="1" />
      <xsd:group ref="EG_FillProperties" minOccurs="0" maxOccurs="1" />
      <xsd:element name="extLst" type="CT_OfficeArtExtensionList"
        minOccurs="0" maxOccurs="1" />
    </xsd:sequence>
    <xsd:attribute name="marL" type="ST_Coordinate32" use="optional"
      default="91440" />
    <xsd:attribute name="marR" type="ST_Coordinate32" use="optional"
      default="91440" />
    <xsd:attribute name="marT" type="ST_Coordinate32" use="optional"
      default="45720" />
    <xsd:attribute name="marB" type="ST_Coordinate32" use="optional"
      default="45720" />
    <xsd:attribute name="vert" type="ST_TextVerticalType" use="optional"
      default="horz" />
    <xsd:attribute name="anchor" type="ST_TextAnchoringType"
      use="optional" default="t" />
    <xsd:attribute name="anchorCtr" type="xsd:boolean" use="optional"
      default="false" />
    <xsd:attribute name="horzOverflow" type="ST_TextHorzOverflowType"
      use="optional" default="clip" />
  </xsd:complexType>
```

5.5.3.2 Column

The complex type, CT_TableCol, defines a table column element. The table column element simply holds the width for a given column in a table along with an element reserved for future extensibility. The complex type is defined as:

```
  <xsd:complexType name="CT_TableCol">
    <xsd:sequence>
      <xsd:element name="extLst" type="CT_OfficeArtExtensionList"
        minOccurs="0" maxOccurs="1" />
    </xsd:sequence>
    <xsd:attribute name="w" type="ST_Coordinate" use="required" />
  </xsd:complexType>
```

5.5.3.3 Table Grid

The complex type, CT_TableGrid, defines a list of table column elements, or rather CT_TableCol complex types. The CT_TableGrid should contain a CT_TableCol for each column in the table and it is defined in the following manner:

```
<xsd:complexType name="CT_TableGrid">
  <xsd:sequence>
    <xsd:element name="gridCol" type="CT_TableCol" minOccurs="0"
      maxOccurs="unbounded" />
  </xsd:sequence>
</xsd:complexType>
```

5.5.3.4 Cell

The complex type, CT_TableCell, defines a cell in a table. Within this complex type lies a text body which holds the data of the cell along with any formatting applied to the text. This complex type also holds a table cell property complex type which has already been defined. The rowSpan and gridSpan attributes are available along with hMerge and vMerge attributes. The hMerge and vMerge attributes define if the current cell is supposed to be merged with the previous cell horizontally or vertically. This is how the table is parsed and created. The complex type, CT_TableCell, is defined as:

```
<xsd:complexType name="CT_TableCell">
  <xsd:sequence>
    <xsd:element name="txBody" type="CT_TextBody" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="tcPr" type="CT_TableCellProperties"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="extLst" type="CT_OfficeArtExtensionList"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="rowSpan" type="xsd:int" use="optional"
    default="1" />
  <xsd:attribute name="gridSpan" type="xsd:int" use="optional"
    default="1" />
  <xsd:attribute name="hMerge" type="xsd:boolean" use="optional"
    default="false" />
  <xsd:attribute name="vMerge" type="xsd:boolean" use="optional"
    default="false" />
</xsd:complexType>
```

5.5.3.5 Row

The complex type, CT_TableRow, defines a table row. This complex type is somewhat more complex than the similar table column complex type in that it holds a sequence of CT_TableCell structures along with a height for the row. The complex type is defined in the following way:

```
<xsd:complexType name="CT_TableRow">
  <xsd:sequence>
    <xsd:element name="tc" type="CT_TableCell" minOccurs="0"
      maxOccurs="unbounded" />
    <xsd:element name="extLst" type="CT_OfficeArtExtensionList"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="h" type="ST_Coordinate" use="required" />
</xsd:complexType>
```

5.5.3.6 Table Properties

The complex type, CT_TableProperties, defines the properties for a table as a whole. Within this complex type is a definition for a table style that is currently applied to the table, or the GUID for the built in table style that is applied to the table. Also in this complex type are right-to-left settings, the effects applied to the table (shadow, reflection, etc), background fill information, and the states for the different on/off table style options. The complex type is defined as:

```
<xsd:complexType name="CT_TableProperties" >
  <xsd:sequence>
    <xsd:group ref="EG_FillProperties" minOccurs="0" maxOccurs="1" />
    <xsd:group ref="EG_EffectProperties" minOccurs="0"
      maxOccurs="1" />
    <xsd:choice oxsd:cname="TableStyleOrLink" minOccurs="0"
      maxOccurs="1" >
      <xsd:element name="tableStyle" type="CT_TableStyle" />
      <xsd:element name="tableStyleId" type="ST_Guid" />
    </xsd:choice>
    <xsd:element name="extLst" type="CT_OfficeArtExtensionList"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="rtl" type="xsd:boolean" use="optional"
    default="false" />
  <xsd:attribute name="firstRow" type="xsd:boolean" use="optional"
    default="false" />
  <xsd:attribute name="firstCol" type="xsd:boolean" use="optional"
    default="false" />
  <xsd:attribute name="lastRow" type="xsd:boolean" use="optional"
    default="false" />
  <xsd:attribute name="lastCol" type="xsd:boolean" use="optional"
    default="false" />
  <xsd:attribute name="bandRow" type="xsd:boolean" use="optional"
    default="false" />
```

```
    <xsd:attribute name="bandCol" oxsdtype="xsd:boolean" use="optional"
      default="false" />
  </xsd:complexType>
```

5.5.3.7 Table

The final complex type, CT_Table, is the root element for a table. This complex type holds all the information that is needed to create a table within DrawingML. Within CT_Table are the table properties, a table grid, and a table row. A CT_Table is defined in the following manner:

```
  <xsd:complexType name="CT_Table">
    <xsd:sequence>
      <xsd:element name="tblPr" type="CT_TableProperties" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="tblGrid" type="CT_TableGrid" minOccurs="1"
        maxOccurs="1" />
      <xsd:element name="tr" type="CT_TableRow" minOccurs="0"
        maxOccurs="unbounded" />
    </xsd:sequence>
  </xsd:complexType>
```

5.6 3D Aspects

5.6.1 Introduction

This subclause provides a high-level overview of the content described in the following schemas: dml-shape3DStyles.xsd, dml-shape3DScene.xsd, dml-shape3DScenePlane.xsd, dml-shape3DLighting.xsd, and dml-shape3DCamera.xsd.

This aspect of DrawingML deals mainly with the 3-D aspects, and can be broken down into two topics: 3-D properties associated with an object, and the styling information associated with an object. The above-mentioned schemas fall into the grouping in the following way:

3-D	Styles
dml-shape3DScene.xsd dml-shape3DScenePlane.xsd dml-shape3DLighting.xsd dml-shape3DCamera.xsd	dml-shape3DStyles.xsd

5.6.2 3-D

Here we'll explain the 3-D definitions contained in DrawingML. The goal here is to define a 3-D scene so that lighting calculations can be made on the geometry within the scene.

5.6.2.1 3-D Scene

Every 3-D scene consists of a camera, a light, and a backdrop, that define the associated properties of the scene. The complex type, CT_Scene3D, defines the scene as follows:

```
<xsd:complexType name="CT_Scene3D" oxsd:cname="Scene3D">
  <xsd:sequence>
    <xsd:element name="camera" type="CT_Camera" minOccurs="1"
      maxOccurs="1" />
    <xsd:element name="lightRig" type="CT_LightRig" minOccurs="1"
      maxOccurs="1/>
    <xsd:element name="backdrop" type="CT_Backdrop" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="ext" type="CT_OfficeArtExtension" minOccurs="0"
      maxOccurs="1" />
  </xsd:sequence>
</xsd:complexType>
```

As was stated above, the complex type, CT_Scene3D, contains a camera, a set of lights (the light rig), and a backdrop. Those familiar with 3-D rendering techniques understand the usage of a camera and set of lights, or light rig. The backdrop, however, is a special structure (which will be defined below) that allows for a special plane to render certain effects that need to be rendered together in a single plane. The final element of a CT_Scene3D is the ext element. This is a DrawingML structure used for future extensibility. This element will be seen in other complex types dealing with the 3-D scene as well.

5.6.2.2 Camera

The complex type, CT_Camera, defines a camera within the 3-D scene. A camera is based on a preset, with an optional rotation, field-of-view, and zoom, which all act as overrides for the preset values. A camera is defined in the following way:

```
<xsd:complexType name="CT_Camera">
  <xsd:sequence>
    <xsd:element name="rot" type="CT_SphereCoords" minOccurs="0"
      maxOccurs="1" oxsd:dataStructure="optional" />
  </xsd:sequence>
  <xsd:attribute name="prst" type="ST_PresetCameraType" use="required"
    />
  <xsd:attribute name="fov" type="ST_FOVAngle" use="optional" />
  <xsd:attribute name="zoom" type="ST_PositivePercentage"
    use="optional" default="100000" />
</xsd:complexType>
```

The only complex type contained in the camera, CT_SphereCoords, is a type defined elsewhere within the DrawingML. There are three simple types associated with a camera:

- ST_FOVAngle (field of view angle), which is a positive angle between 0 and 180 in 60,000th of a degree.
- ST_PositivePercentage (zoom), which is defined as a percentage in 1,000th of a percent.
- ST_PresentCameraType (preset camera)

Figure 1 below shows some different presets applied to a shape.

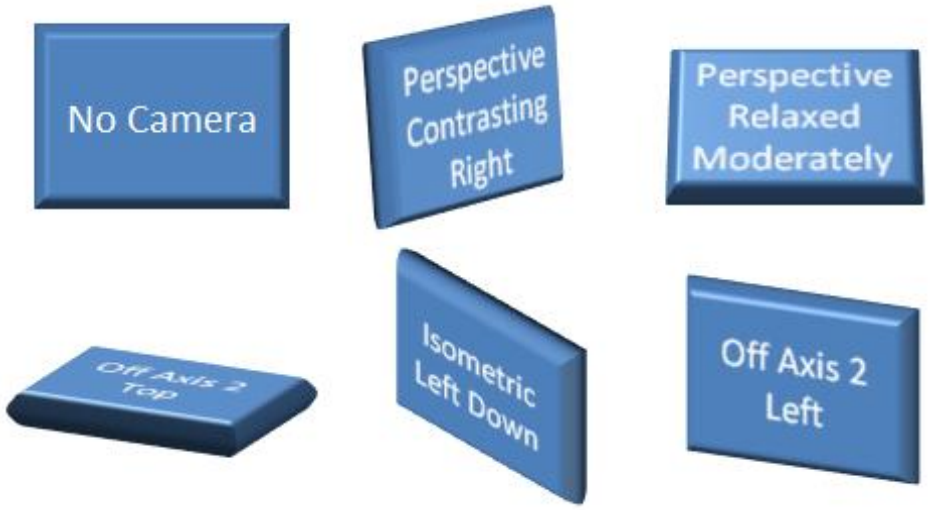


Figure 7: Different default cameras applied to a shape

5.6.2.3 Light

The complex type, CT_LightRig, defines the lighting of the scene. A light rig consists of a preset direction, preset rig type, and a rotation that serves as an override for the direction. The complex type is defined as:

```
<xsd:complexType name="CT_LightRig">
  <xsd:sequence>
    <xsd:element name="rot" type="CT_SphereCoords" minOccurs="0"
      maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="rig" type="ST_LightRigType" use="required" />
  <xsd:attribute name="dir" type="ST_LightRigDirection" use="required"}
    />
</xsd:complexType>
```

Just as with the camera, the complex type, CT_SphereCoords, is defined elsewhere in the DrawingML. This element, however, serves as an override for the default light right direction. Figure 2 below shows some of the different preset lights applied to a shape.

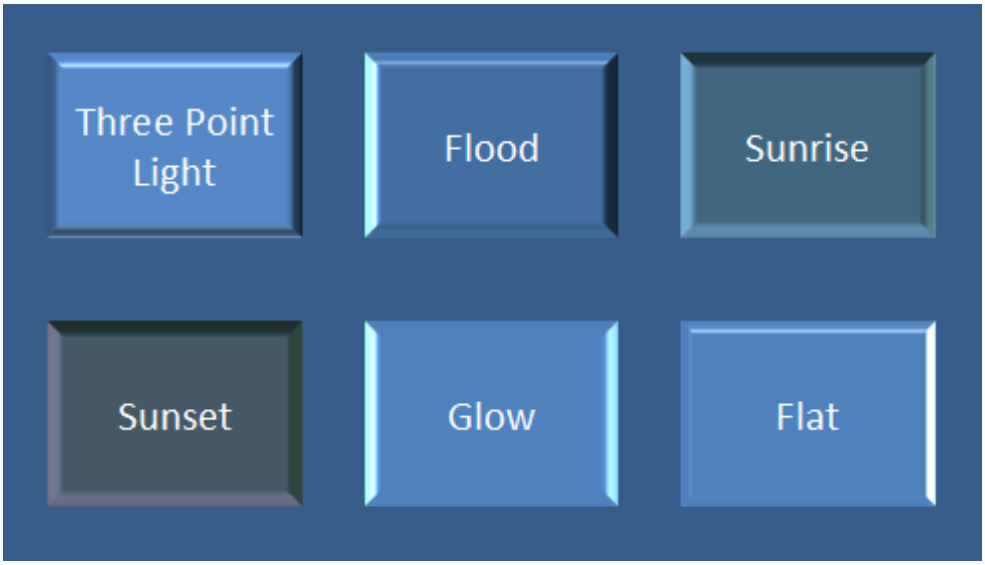

Figure 8: Some preset lights applied to a shape.

The types of available light rigs are:

legacyFlat1
legacyFlat2
legacyFlat3

legacyFlat4

The types of available present directions are:

tl – top left
t – top
tr – top right
l – left

r – right
bl – bottom left
b – bottom
br – bottom right

5.6.2.4 Backdrop

The complex type, CT_Backdrop, defines a unique place in the 3-D scene. The backdrop is a flat 2-D plane that can hold effects, such as shadows, oriented in 3-D space. The points and vectors contained within the backdrop are relative to world space. The complex type is defined as:

```
<xsd:complexType name="CT_Backdrop">
  <xsd:sequence>
    <xsd:element name="anchor" type="CT_Point3D" minOccurs="1"
      maxOccurs="1" />
    <xsd:element name="norm" type="CT_Vector3D" minOccurs="1"
      maxOccurs="1" />
    <xsd:element name="up" type="CT_Vector3D" minOccurs="1"
      maxOccurs="1"/>
    <xsd:element name="ext" type="CT_OfficeArtExtension" minOccurs="0"
      maxOccurs="1" />
  </xsd:sequence>
</xsd:complexType>
```

All of the complex types defined within this backdrop are defined elsewhere in DrawingML. As with other complex types, the backdrop also contains an element reserved for future extensibility.

5.6.3 Styles

The 3-D styles section encompasses the properties for 3-D shapes. These properties are those that get applied to the 3-D shape, such as a bevel or a contour, and they define the look of the shape in 3-D. A number of simple types used within the complex types of this group are defined below.

5.6.3.1 Simple Types

The simple types defined here outline the different presets available to the user. These presets are applied to the shapes through the complex type definitions that are outlined later.

5.6.3.1.1 Bevel Type

The simple type, ST_BevelPresetType, defines a preset bevel for a shape and some examples can be seen in figure 3.

Figure 9: Different bevel types applied to a shape

The different types of bevels available are:

relaxedInset
circle
slope
cross
angle
softRound

convex
coolSlant
divot
riblet
hardedge
artDeco

5.6.3.1.2 Preset Material Type

The simple type, ST_PresetMaterialType, defines a material for the shape. The material properties describe the surface appearance of the shape, and are used in lighting calculations to define exactly how the light interacts with the shape. Some example material types can be seen in figure 4.

Figure 10: Different material types on a shape.

The different preset material types are:

legacyMatte
legacyPlastic
legacyMetal
legacyWireframe
matte

plastic
metal
warmMatte
translucentPowder
powder

dkEdge
softEdge
clear
flat
softMetal

5.6.3.2 Complex Types

The complex types in this area define the actual 3-D properties that get applied to a shape. These properties work together in order to define the geometry of a shape along with the scene related properties that define the look of the geometry of the shape.

5.6.3.2.1 Bevel

The complex type, CT_Bevel, defines a bevel for a shape. The bevel consists of a width and a height value, along with a preset bevel. The complex type is defined in the following manner:

```
<xsd:complexType name="CT_Bevel">
  <xsd:attribute name="w" type="ST_PositiveCoordinate" use="optional"
    default="76200" />
  <xsd:attribute name="h" type="ST_PositiveCoordinate" use="optional"
    default="76200" />
  <xsd:attribute name="prst" type="ST_BevelPresetType" use="optional"
    default="circle" />
</xsd:complexType>
```

5.6.3.2.2 Shape 3-D

The complex type, CT_Shape3D, defines all of the 3-D properties associated with an individual shape. A shape can have two bevels, one on the top and one on the bottom. An extrusion color also defined, which, when applied, applies a color to the surface of the extrusion. There is also an extrusion width, which defines the width of the extrusion. A contour color and width can be defined for the shape. A z-axis anchor is defined within the complex type and is the anchor relative to the shape's top face. The shape 3-D complex type also holds a present material. Finally the shape 3-D contains another element just as in previous complex types, which is used for future extensibility. The CT_Shape3D complex type is defined in the following manner:

```
<xsd:complexType name="CT_Shape3D">
  <xsd:sequence>
    <xsd:element name="bevelT" type="CT_Bevel" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="bevelB" type="CT_Bevel" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="extrusionClr" type="CT_Color" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="contourClr" type="CT_Color" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="ext" type="CT_OfficeArtExtension" minOccurs="0"
      maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="z" type="ST_Coordinate" use="optional"
    default="0" />
  <xsd:attribute name="extrusionH" type="ST_PositiveCoordinate"
    use="optional" default="0" />
  <xsd:attribute name="contourW" type="ST_PositiveCoordinate"
    use="optional" default="0" />
  <xsd:attribute name="prstMaterial" type="ST_PresetMaterialType"
    use="optional" default="warmMatte" />
</xsd:complexType>
```

5.6.3.2.3 Flat Text

The complex type, CT_FlatText, defines a text object in a 3-D scene that should be rendered as a normal, flat, text overlay outside of the 3-D scene. The complex type is defined in the following manner:

```
<xsd:complexType name="CT_FlatText">
  <xsd:attribute name="z" type="ST_Coordinate" use="optional"
    default="0" />
</xsd:complexType>
```

5.6.3.2.4 Group, Text 3-D

The final structure to be defined is a group, EG_Text3D, which describes how text should be applied in the 3-D scene. If the text object is a member of the 3-D scene, then there are three different ways it can be displayed:

- If no EG_Text3D choice is provided, the text will be rendered in a scene coherent manner and will be rendered in perspective inside of the 3D scene as a planar shape inside the 3-D.
- If CT_Shape3D is provided then the text will be scene coherent and fully 3-D.
- If CT_FlatText is provided then the text will be drawn as normal 2-D text rendered on top of the 3-D scene.

An EG_Text3D is defined in the following manner:

```
<xsd:group name="EG_Text3D">
  <xsd:choice oxsd:cname="Text3DChoice"
    oxsd:cnameMember="text3DChoice">
    <xsd:element name="sp3dtype="CT_Shape3D" minOccurs="1"
      maxOccurs="1/>
    <xsd:element name="flatTx" type="CT_FlatText" minOccurs="1"
      maxOccurs="1" />
  </xsd:choice>
</xsd:group>
```

5.7 Coordinate Systems and Transformations

5.7.1 Introduction

This document provides an overview of the transformation elements for shapes and groups, represented by <a:xfrm>in dml-baseTypes.xsd. These schemas are for the representation of scaling and rotation on individual shapes and groups.

§5.7.2, §5.7.3, and §5.7.4 provide a qualitative overview of the transformation pipeline. §5.7.6 provides mathematical details.

5.7.2 Coordinate System

All DrawingML shapes are located on a 2-D Cartesian coordinate space with the origin (0,0) in the upper left-hand corner of the canvas. The x-axis coordinates grow positively as one moves from left to right, and the y-axis coordinates grow positively as one moves from top to bottom.

Coordinates are measured in EMUs (914400 EMUs per inch), and can be positive or negative.

5.7.3 Shape Transformations

In this subclause, we describe the transformation pipeline for a shape. To summarize, the *shape transformation* for a shape is defined as the following sequence of operations:

1. The translation and scaling required to transform its original bounding box to a rectangle specified by the offset and extents.
2. A flip across the center of the bounding box according to flipH and flipV.
3. A rotation about the center of the bounding box according to the rot attribute.

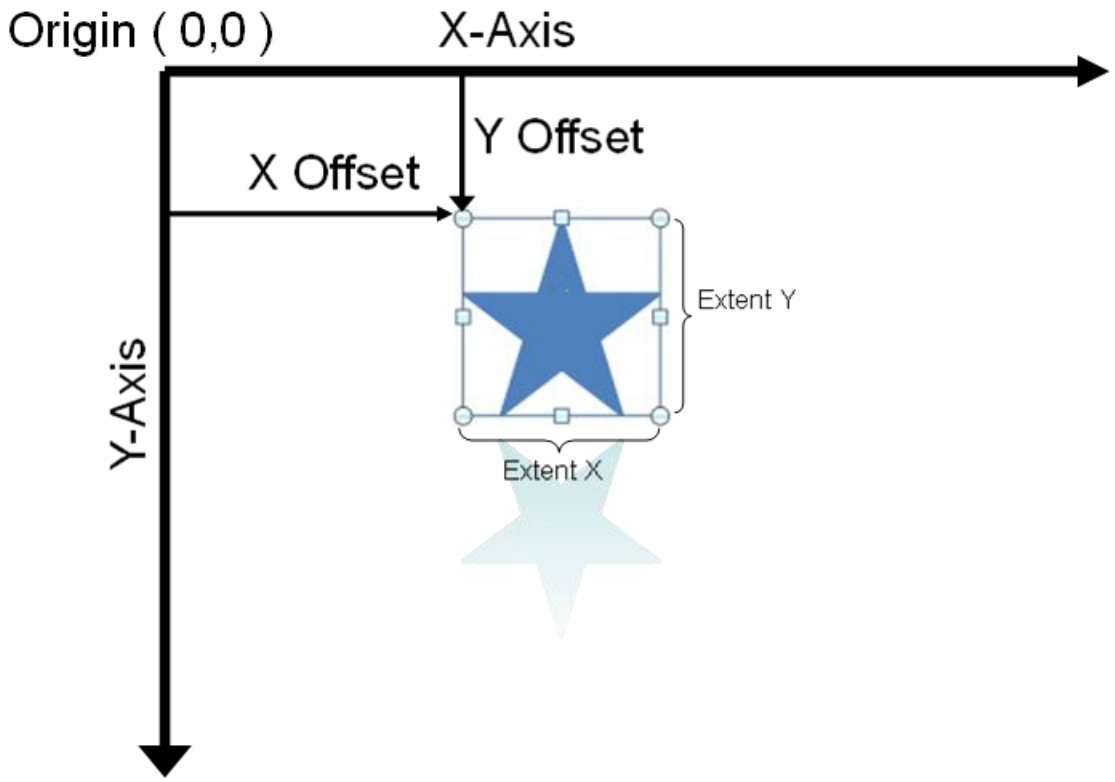
To render a shape that is not inside a group (§5.7.4), the renderer simply applies the shape transformation to the original shape.

5.7.3.1 Scaling and Translating a Shape

The shape is scaled horizontally, scaled vertically, and translated in both dimensions, to fill a given bounding box. The bounding box is represented by specifying an offset in x and y (attributes x and y of a:off) and extents in x and y (attributes cx and cy of a:ext, both of which must be greater than or equal to zero). The upper left

corner of the bounding box is located at the offset, and the lower right corner of the bounding box is located at the offset plus extent.

If the starting shape has zero width (e.g., it is a vertical line), then the cx attribute of a:ext is ignored and the horizontal scaling is skipped. Similarly, if the starting shape has zero height, then the cy attribute of a:ext is ignored and the vertical scaling is skipped.



The following XML fragment represents the offset and extents for the star shape above:

```
<a:xfrm>
  <a:off x="1866680" y="990600"/>
  <a:ext cx="1371600" cy="1371600"/>
</a:xfrm>
```

Notice that as demonstrated with the example above, any effects attached to the shape are disregarded when scaling and translating the shape to fill the given bounding box.

This example illustrates that no additional parameters are needed to represent the scaling of a shape. The bounding-box parameters are sufficient to represent scaling. The following XML Fragments represent the offset and extents for a star shape, before and after scaling. In this particular example, the bounding boxes have been chosen to have the same upper-left corner, i.e., the same offset.

Before scaling (small star):

```
<a:xfrm>
  <a:off x="1066800" y="990600"/>
  <a:ext cx="1371600" cy="1371600"/>
</a:xfrm>
```

After scaling (large star):

```
<a:xfrm>
  <a:off x="1066800" y="990600"/>
  <a:ext cx="2438400" cy="2133600"/>
</a:xfrm>
```

5.7.3.2 Rotating a Shape

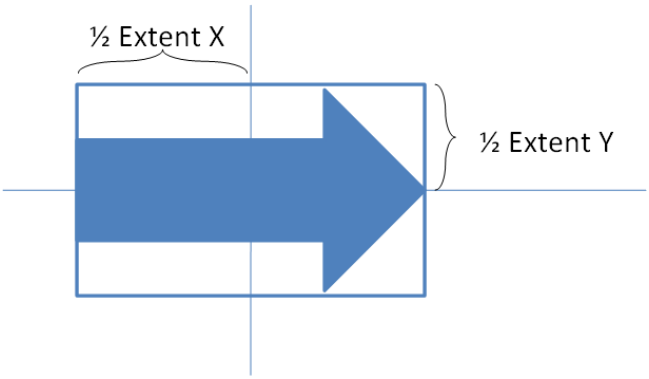
Rotation is represented with the rot attribute. The shape is rotated clockwise about the bounding-box center, by the amount specified in the rot attribute. Each unit of rotation is 1/1,000 of an arc minute (1/60,000 of a degree).

This example represents the small star from above, with a subsequent 45-degree rotation clockwise. Since the y axis points down, a clockwise rotation is positive.

```
<a:xfrm rot="2700000">
  <a:off x="1066800" y="990600"/>
  <a:ext cx="1371600" cy="1371600"/>
</a:xfrm>
```

5.7.3.3 Flipping a Shape

A flip is a reflection across a vertical or horizontal line that intersects the center of the bounding box. The optional flipH and flipV attributes control horizontal and vertical flipping, respectively. Each is absent or equal to `0` if no flipping is to be performed, and equal to `1` if flipping is to be performed.



The following XML fragment illustrates a shape that has been flipped both horizontally and vertically.

```
<a:xfrm flipH="1" flipV="1">
  <a:off x="3964937" y="2652643"/>
  <a:ext cx="168838" cy="1219199"/>
</a:xfrm>
```

5.7.4 Group Transformations

A group is composed of zero to many shapes. Because a group is a shape, this composition relationship can nest recursively. (A group with zero shapes is degenerate; it produces no user-visible output. A group with one shape is also degenerate; it has no representational power beyond that of the one shape.)

The definition of a group transformation is identical to that of a shape transformation, except that in place of the pre-transform bounding box of a shape, we use the union of all of its children prior to their individual rotations. To summarize, a *group transformation* is the following sequence of operations:

1. The translation and scaling required to transform the union of the children's bounding boxes to a rectangle defined by the group's offset and extent attributes.
2. A flipped about that bounding box according to the flipH and flipV attributes.
3. A rotation about the center of that bounding box according to the rot attribute.

To render a simple shape that is inside a group hierarchy, the renderer does not simply apply the shape transformation and all parent group transformations to the original shape. Instead (see §5.7.5), it applies the transformation equal to the following sequence of operations:

1. Horizontal scaling and flipping by a factor equal to the product of the horizontal scalings and flips in its own transformation and those of its parents.
2. Vertical scaling and flipping by a factor equal to the product of the vertical scalings and flips in its own transformation and those of its parents.
3. Rotation by an amount equal to the sum of the rotations in its own transformation and those of its parents.
4. Translation such that its center coincides with the point obtained by applying the shape transformation and all parent group transformations to the shape's original center.

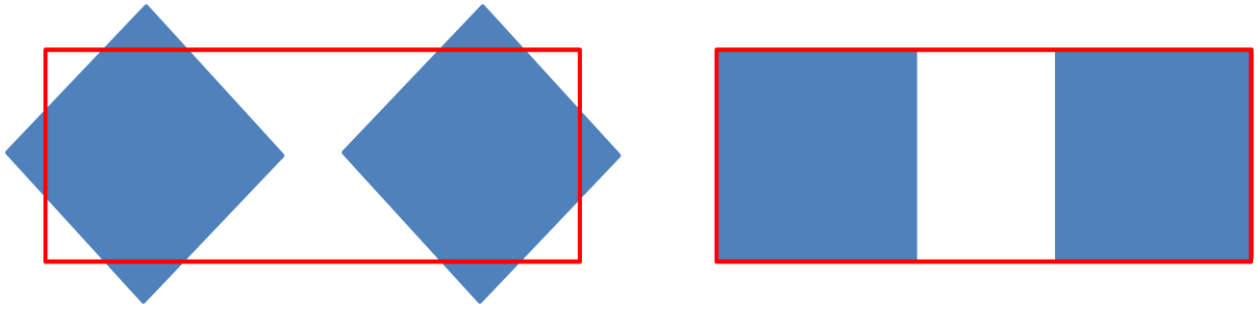
Because of the similarity with the transformation pipeline for a shape, the forthcoming subsections primarily cover illustrative examples.

5.7.4.1 Scaling and Translating a Group

The group is scaled horizontally, scaled vertically, and translated in both dimensions. The parameters are chosen to transform the child bounding box (specified by a:chOff and a:chExt) to the group bounding box (specified by a:off and a:ext). The *child bounding box* is defined as the bounding box around the group's children as they would have been had their rot attributes been absent.

It is possible for the child bounding box to have a zero value for cx or cy in a:chExt, e.g., because the starting shape is a horizontal or vertical line, or because the starting shape was scaled to have zero width or height. Such a case is handled in the same way as previously described for simple shapes.

This example demonstrates the definition of the child bounding box. The two shapes on the left, rotated squares, are grouped. The two shapes on the right, non-rotated squares, are also grouped.



The red bands are not part of the drawing; each represents the child bounding box of a group. In the XML fragments, the child bounding boxes have identical y values, illustrating that they are computed based on the bounding boxes of the squares prior to their rotation.

For the left-hand group:

```
<a:xfrm>
  <a:off x="762000" y="1828800" />
  <a:ext cx="3327400" cy="1219200" />
  <a:chOff x="762000" y="1828800" />
  <a:chExt cx="3327400" cy="1219200" />
</a:xfrm>
```

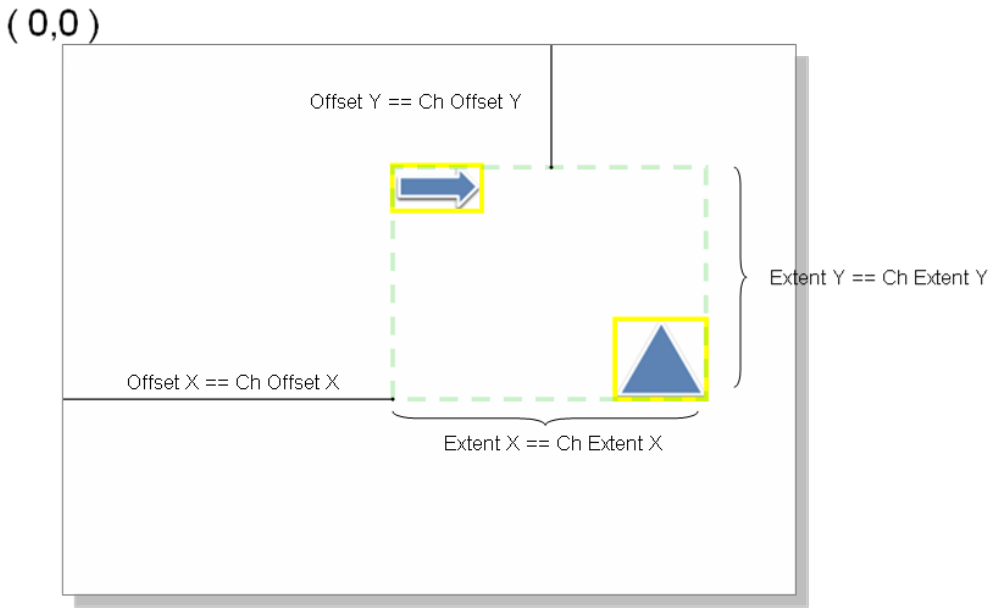
For the right-hand group:

```
<a:xfrm>
  <a:off x="4978400" y="1828800" />
  <a:ext cx="3327400" cy="1219200" />
  <a:chOff x="4978400" y="1828800" />
  <a:chExt cx="3327400" cy="1219200" />
</a:xfrm>
```

The remainder of the examples in this subsection illustrate translation and scaling of a group.

In this situation, two shapes are grouped: an arrow and a triangle. No further translation, scaling, rotation, or flipping is applied.

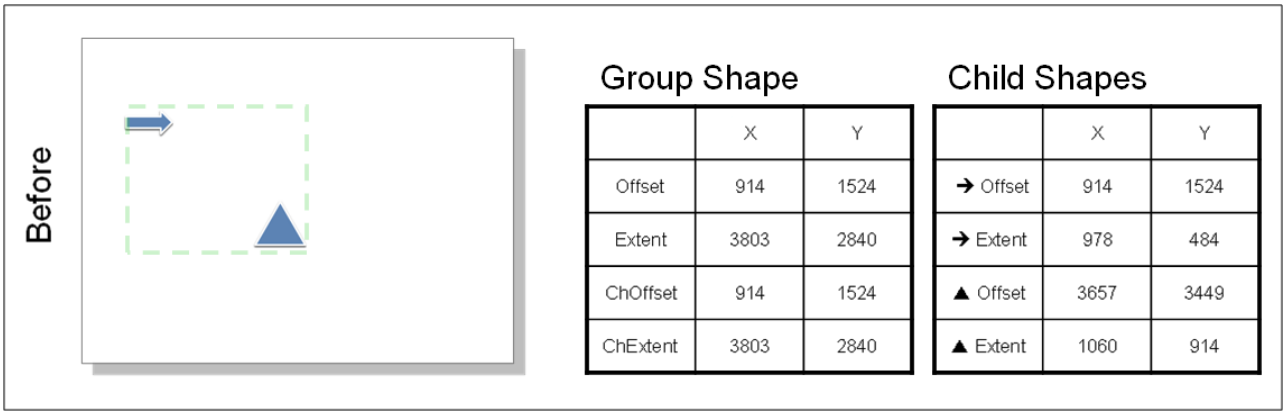
To represent this situation, the child bounding box is the bounding box around both of these shapes; and because no further transformation is applied, the group bounding box is equal to the child bounding box.



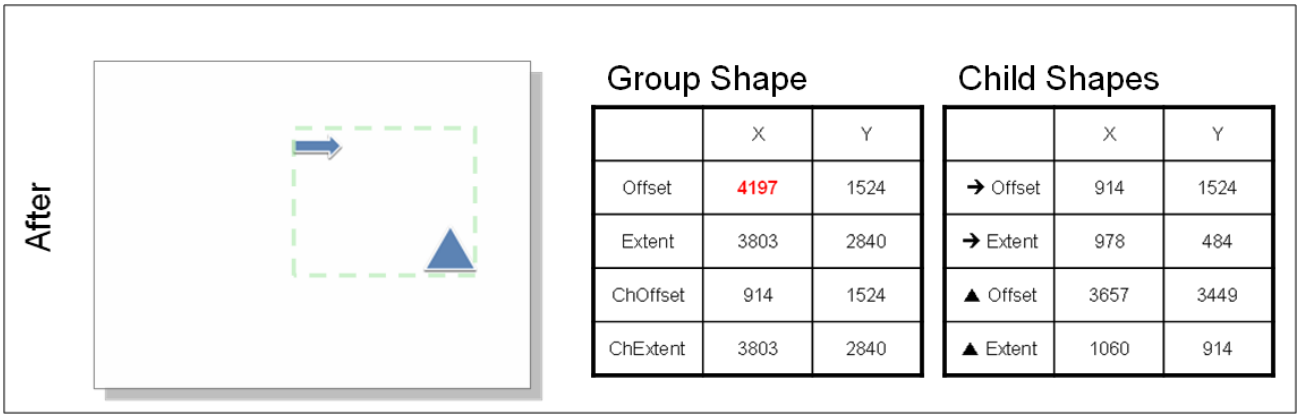
The following is an XML snippet representing the transform variables of the group.

```
<p:grpSpPr>
  <a:xfrm>
    <a:off x="2209800" y="2514600"/>
    <a:ext cx="4038600" cy="2286000"/>
    <a:chOff x="2209800" y="2514600"/>
    <a:chExt cx="4038600" cy="2286000"/>
  </a:xfrm>
</p:grpSpPr>
```

This example illustrates that no additional parameters are needed to represent the translation of a group. A group is moved to the right. The following diagram shows the starting state, prior to the translation. Note that offset==ChOffset and extent==ChExtent.



Increasing the x component of the offset moves the group to the right.

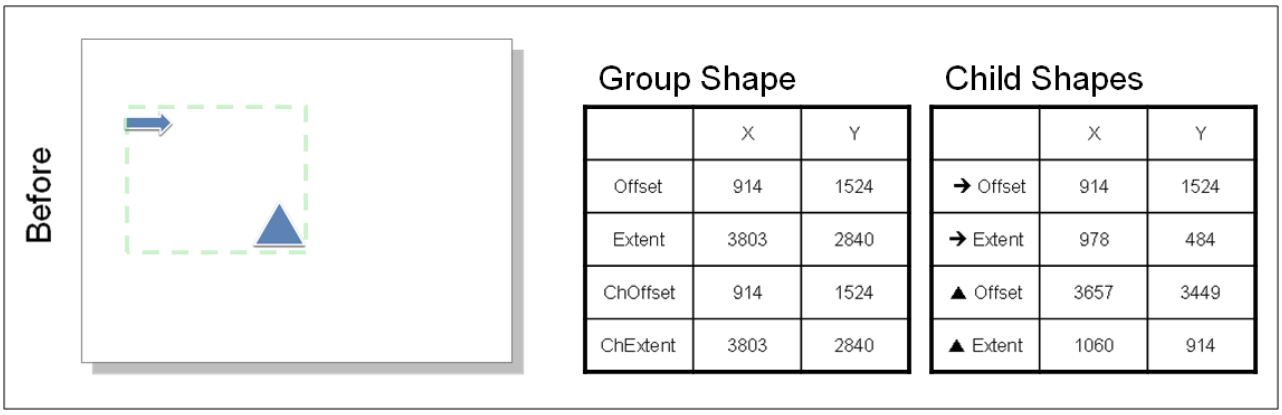


Similarly, scaling can be performed by adjusting the group bounding box.

5.7.4.2 Rotating a Group

Group rotation is identical to shape rotation. The group is rotated clockwise about the bounding-box center, by the amount specified in the rot attribute.

In this example, group is rotated 90 degrees clockwise. The following diagram shows the starting state, prior to the rotation.



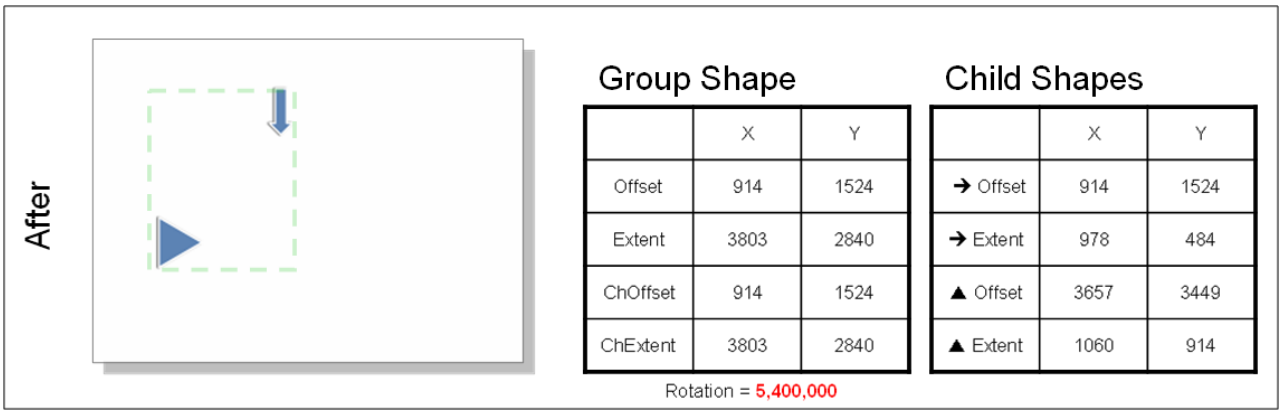
Group Shape

	X	Y
Offset	914	1524
Extent	3803	2840
ChOffset	914	1524
ChExtent	3803	2840

Child Shapes

	X	Y
→ Offset	914	1524
→ Extent	978	484
▲ Offset	3657	3449
▲ Extent	1060	914

Setting the rotation attribute to 5,400,000 rotates the group clockwise 90 degrees.



Group Shape

	X	Y
Offset	914	1524
Extent	3803	2840
ChOffset	914	1524
ChExtent	3803	2840

Child Shapes

	X	Y
→ Offset	914	1524
→ Extent	978	484
▲ Offset	3657	3449
▲ Extent	1060	914

Rotation = 5,400,000

5.7.5 Nesting Transformations

The following example illustrates the rendering procedure described at the end of the introduction to §5.7.4, which differs from a conventional transformation pipeline in any case where a scaled group contains a rotated child.

[Example: In this example, the diagram on the left side is a group that comprises a rotated red square centered inside a non-rotated blue square. The diagram on the right side is the same group, scaled horizontally. The red square scales along an axis parallel to its own edges instead of an axis parallel to the edges of the blue square.

5.7.6 Transformation Matrices

The preceding sections fully define the transformation pipeline and its parameters. This section assists developers in implementing the pipeline by describing it mathematically. It is generalized to describe either the shape transformation pipeline or the group transformation pipeline.

5.7.6.1 Symbol Definitions

Let the following symbols represent parameters described in the preceding sections.

(B_x, B_y)	For a shape: upper left corner of untransformed shape. For a group: upper left corner of child bounding box (a:chOff).
(D_x, D_y)	For a shape: (width,height) of untransformed shape. For a group: (width,height) of child bounding box (a:chExt).
(B'_x, B'_y)	Upper left corner of bounding box (a:off), prior to rotation and flip.
(D'_x, D'_y)	(width,height) of bounding box (a:ext), prior to rotation and flip.
θ	Clockwise rotation (from the attribute rot, which uses thousandths of an arc minute).
F_x	−1 if flipH is true; +1 otherwise.
F_y	−1 if flipV is true; +1 otherwise.

We use homogeneous coordinates, in which a point p is represented in the form

$$p = \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} .$$

We use the convention in which transformations are applied by left-hand multiplication. Thus, to obtain the point p' by applying transformation T to point p we write:

$$p' = T\,p$$

5.7.6.2 Transformation Pipeline

The entire transformation pipeline that defines either a shape transformation or a group transformation is represented by the matrix T, defined at the end of this subsection.

Scaling and translation are produced by the following matrix:

$$T_{st} = \begin{bmatrix} \frac{D'_x}{D_x} & 0 & B'_x - \left(\frac{D'_x}{D_x}\right) B_x \\ 0 & \frac{D'_y}{D_y} & B'_y - \left(\frac{D'_y}{D_y}\right) B_y \\ 0 & 0 & 1 \end{bmatrix} .$$

The following matrix translates the bounding box to the origin in preparation for rotation and flipping:

$$U = \begin{bmatrix} 1 & 0 & -\left(B'_x + \frac{D'_x}{2}\right) \\ 0 & 1 & -\left(B'_y + \frac{D'_y}{2}\right) \\ 0 & 0 & 1 \end{bmatrix} .$$

Rotation and flipping are produced by the following matrix:

$$T_{rf} = U^{-1} \begin{bmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} F_x & 0 & 0 \\ 0 & F_y & 0 \\ 0 & 0 & 1 \end{bmatrix} U .$$

The entire transformation pipeline for one step in the group hierarchy is represented by the matrix

$$T = T_{rf} T_{st}$$

5.8 Shape Properties and Effects

5.8.1 Introduction

This subclause provides a high-level overview of the Fill Properties, Line Properties, and Effect Properties described in the following schemas: dml-shapeLineProperties.xsd, dml-shapeEffects.xsd, dml-baseTypes.xsd.

Color Models are also covered, as Fills, Lines, and Effects all reference color model schemas to represent color.

5.8.2 Color Models

There are several methods of expressing color: scrgbClr, srgbClr, hslClr, sysClr, schemeClr, and prstClr. Although srgbClr is the most commonly used model, the rationale for having various equivalent color models stems from a desire to have different ways of naturally expressing a color choice.

5.8.2.1 scrgbClr

scrgbClr is a legacy form of expressing Red, Green, Blue color. Values are expressed in Percentages. r, g, and b are all required and correspond to red, green, and blue, respectively.

```
<a:scrgbClr r="10000" g="20000" b="30000">
```

5.8.2.2 srgbClr

srgbClr is similar to scrgbClr with the exception that instead of expressing the values as percentages, they are specified using two hex digits per color, in the order RGB.

```
<a:srgbClr val="FFFF00">
```

5.8.2.3 hslClr

hslClr represents a color using the Hue, Saturation, and Luminescence color model. Values are expressed in Percentages. h, s, and l are all required, and correspond to hue, saturation, and luminescence respectively. A perceptual gamma of 2.2 is assumed.

```
<a:hslClr h="10000" s="20000" l="30000">
```

5.8.2.4 sysClr

sysClr represents a system color, and introduces a level of indirection. For example, specifying:

```
<a:sysClr val="windowText">
```

binds the color to be the color chosen in the system for "Window Text". The possible values are:

```
scrollBar
background
activeCaption
inactiveCaption
menu
window
windowFrame
menuText
windowText
captionText
activeBorder
inactiveBorder
appWorkspace
highlight
highlightText
btnFace
btnShadow
grayText
btnText
inactiveCaptionText
btnHighlight
3dDkShadow
3dLight
infoText
infoBk
hotLight
gradientActiveCaption
gradientInactiveCaption
menuHighlight
menuBar
```

5.8.2.5 schemeClr

schemeClr represents a color from a theme. The color changes if theme bindings change. For example, specifying:

```
<a:schemeClr val="lt1">
```

binds the color to be Light 1 color of the current theme. The possible values are:

bg1	semantic background color
bg1	semantic background color
tx1	semantic text color
bg2	semantic additional background color
tx2	semantic additional text color
accent1	extra scheme color 1
accent2	extra scheme color 2
accent3	extra scheme color 3
accent4	extra scheme color 4
accent5	extra scheme color 5
accent6	extra scheme color 6
hlink	hyperlink color
folHlink	followed hyperlink color
dk1	main dark color 1
lt1	Main light color 1
phClr	a color used in theme definitions which means "use the color of the style"
dk2	main dark color 2
lt2	main light color 2

5.8.2.6 prstClr

prstClr represents a preset color. This is a legacy definition of colors which is no longer currently used. A preset color is a choice from among several presets provided in older versions of Office.

```
<a:prstClr val="black">
```

The selected color is "black". Valid values for this setting are:

```
aliceBlue
antiqueWhite
aqua
aquamarine
azure
beige
bisque
black

5.8.3 Color Transforms

A color transform is a modification to related properties of an underlying color. For example, transparency is a property that is related to color. Color transforms are specified as child tags off any color model's tag.

```
<a:solidFill>
  <a:srgbClr val="00B050">
    <a:alpha val="51000"/>
  </a:srgbClr>
</a:solidFill>
```

The following are the allowed color transforms and descriptions of the transformations they apply:

- tint: Yields a lighter version of its input color. A 10% tint is 10% of the input color combined with 90% white.
- shade: Yields a darker version of its input color. A 10% shade is 10% of the input color combined with 90% black.
- comp: Yields the complement of its input color. For example, the complement of red is green.
- inv: Yields the inverse of its input color. For example, the inverse of red (1,0,0) is cyan (0,1,1).
- gray: Yields a grayscale of its input color, taking into relative intensities of the red, green, and blue primaries.
- alpha: Yields its input color with the specified opacity, but with its color unchanged.

- alphaOff: Yields a more or less opaque version of its input color. An alpha offset never increases the alpha beyond 100% or decreases below 0%; i.e., the result of the transform pins the alpha to the range of [0%,100%]. A 10% alpha offset increases a 50% opacity to 60%. A -10% alpha offset decreases a 50% opacity to 40%.
- alphaMod: Yields a more or less opaque version of its input color. An alpha modulate never increases the alpha beyond 100%. A 200% alpha modulate makes a input color twice as opaque as before. A 50% alpha modulate makes a input color half as opaque as before.
- hue: Yields the input color with the specified hue, but with its saturation and luminance unchanged.
- hueOff: Yields the input color with its hue shifted, but with its saturation and luminance unchanged.
- hueMod: Yields the input color with its hue modulated by the given percentage.
- sat: Yields the input color with the specified saturation, but with its hue and luminance unchanged. Typically saturation values fall in the range [0%, 100%].
- satOff: Yields the input color with its saturation shifted, but with its hue and luminance unchanged.
- satMod: Yields the input color with its saturation modulated by the given percentage. A 50% saturation modulate will reduce the saturation by half. A 200% saturation modulate will double the saturation.
- lum: Yields the input color with the specified luminance, but with its hue and saturation unchanged. Typically, luminance values fall in the range [0%,100%].
- lumOff: Yields the input color with its luminance shifted, but with its hue and saturation unchanged.
- lumMod: Yields the input color with its luminance modulated by the given percentage. A 50% luminance modulate will reduce the luminance by half. A 200% luminance modulate will double the luminance.
- red: Yields the input color with the specified red component, but with its green and blue components unchanged.
- redOff: Yields the input color with its red component shifted, but with its green and blue components unchanged.
- redMod: Yields the input color with its red component modulated by the given percentage. A 50% red modulate will reduce the red component by half. A 200% red modulate will double the red component.
- green: Yields the input color with the specified green component, but with its red and blue components unchanged.
- greenOff: Yields the input color with its green component shifted, but with its red and blue components unchanged.
- greenMod: Yields the input color with its green component modulated by the given percentage. A 50% green modulate will reduce the green component by half. A 200% green modulate will double the green component.
- blue: Yields the input color with the specified blue component, but with its red and green components unchanged.
- blueOff: Yields the input color with its blue component shifted, but with its red and green components unchanged.

- blueMod: Yields the input color with its blue component modulated by the given percentage. A 50% blue modulate will reduce the blue component by half. A 200% blue modulate will double the blue component.
- gamma: Yields the sRGB gamma shift of its input color.
- invGamma: Yields the inverse sRGB gamma shift of its input color.

5.8.4 Fills

There are six types of fills:

- No Fill
- Solid Fill
- Gradient Fill
- Blip Fill
- Pattern Fill
- Group Fill

The se types describe the general structure of all fills; however, not all fills are permitted in all locations. For example, Blip Fills and Group Fills are not permitted on lines.

5.8.4.1 Solid Fills

```
<p:sp>
  <p:nvSpPr>...
  <p:spPr>
    <a:xfrm>
      <a:off x="5410200" y="2438400"/>
      <a:ext cx="2895600" cy="304800"/>
    </a:xfrm>
    <a:prstGeom prst="rect">
      <a:avLst/>
    </a:prstGeom>
    <a:solidFill>
      <a:srgbClr val="FFFF00"/>
    </a:solidFill>
  </p:spPr>
  <p:style>...
  <p:txBody>...
</p:sp>
```

A solid fill specifies a single color, using any valid color model

5.8.4.2 Gradient Fills

```
<a:gradFill>
  <a:gsLst>
    <a:gs pos="69000">
      <a:schemeClr val="accent1"/>
    </a:gs>
    <a:gs pos="0">
      <a:scrgbClr r="0" g="0" b="0"/>
    </a:gs>
  </a:gsLst>
  <a:lin ang="2700000" scaled="1"/>
</a:gradFill>
```

Gradient Stop List

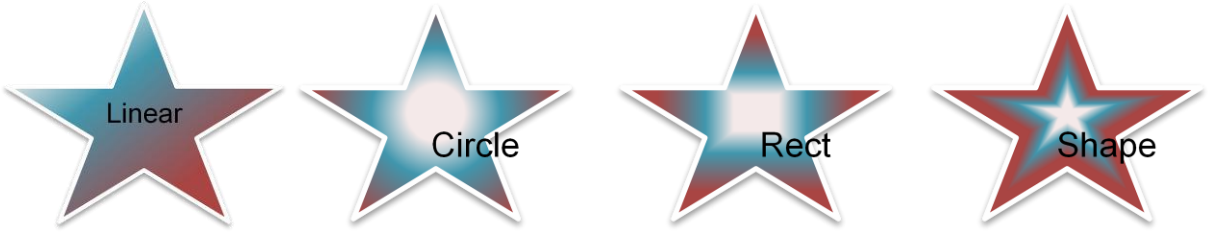
Gradient Fills consist of three elements: a list of gradient stops, a shading specification, as well as some attributes.

Two attributes are available on gradient fills.

- flip specifies how to flip a tile region when using it to fill a larger fill region.
- rotWithShape specifies whether the fill rotates along with a shape when the shape is rotated.

A gradient stop list is a list of locations and colors that make up the gradient fill. Positions are specified as percentages.

The shading specification specifies the two possible kinds of gradient fills: linear, or path based. A linear fill follows a straight-line direction as specified by the angle of the line. A path-based fill follows the contours of a well-defined path (such as a shape, circle, or rectangle).



5.8.4.3 Blip Fills

```
<p:blipFill>
  <a:blip r:embed="rId4" r:link=""/>
  <a:srcRect l="11000" t="14000"
             r="20000" b="28667"/>
  <a:stretch>
    <a:fillRect/>
  </a:stretch>
</p:blipFill>
```

BLIPs refer to Binary Large Image or Pictures. Blip Fills are made up of several components: a Blip Reference, a Source Rectangle, and a Fill Mode.

The Blip reference, a:blip, is the main reference to the blip content itself. A reference ID serves as the main link with an attribute allowed to specify compression level of the blip (one of: email, screen, print, hqprint, none). A Blip Effect may optionally be specified to indicate a modification of the raw blip content. Valid Blip Effects are:

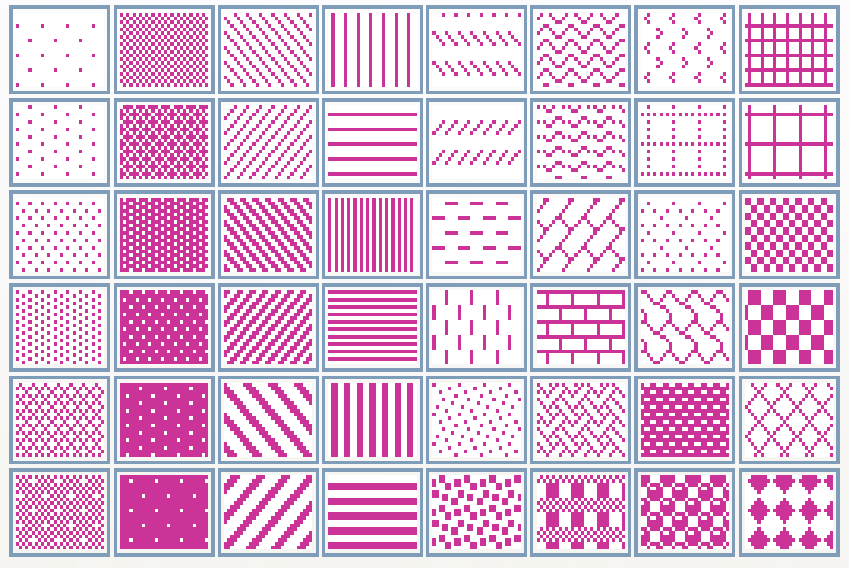
- alphaBiLevel
- alphaCeiling
- alphaFloor
- alphaInv
- alphaMod
- alphaModFix
- alphaRepl
- biLevel
- blur
- clrChange
- clrRepl
- duotone
- fillOverlay
- grayscl
- hsl
- lum
- tint

The blip effects mirror the color transformations (see the descriptions in the color transformations subclause for descriptions of Blip Effects).

A Source Rectangle, a:srcRect, is used to implement image cropping, and indicates the rectangular window of content which is of interest.

Finally, two fill modes are possible, tiling, and stretching. This indicates the behavior to be performed when the user resizes an image to an area larger than the source rectangle. Tiling 'tiles' an image so that image content is simply duplicated while stretching scales the source rectangle content to fill the bounds of the fillRect (bounding box of blip filled shape).

5.8.4.4 Pattern Fills



Pattern Fills are legacy Office 11 fills which consist of a Foreground Color, a Background Color and a preset pattern value. Possible pattern values are:

```
pct5
pct10
pct20
pct25
pct30
pct40
pct50
pct60
pct70
pct75
pct80
pct90
horz

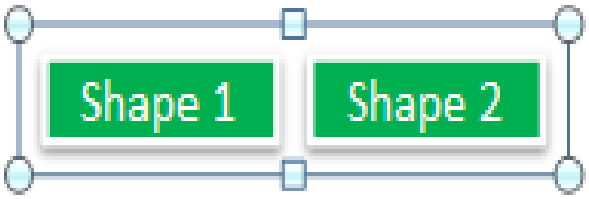
lgConfetti
horzBrick
diagBrick
solidDmnd
openDmnd
dotDmnd
plaid
sphere
weave
divot
shingle
wave
trellis
zigZag
```

5.8.4.5 Group Fills

When objects are grouped together, a group fill is a convenient structure for indicating that the fill properties of any individual element inherits from the fill properties of parent group.

```
<p:grpSp>
  <p:nvGrpSpPr>...
  <p:grpSpPr>
    <a:xfrm>...
    <a:solidFill>
      <a:srgbClr val="00B050"/>
    </a:solidFill>
  </p:grpSpPr>
  <p:sp>
    <p:nvSpPr>...
    <p:spPr>
      <a:xfrm>...
      <a:prstGeom prst="rect">...
      <a:grpFill/>
    </p:spPr>
    <p:style>...
    <p:txBody>...
  </p:sp>
  <p:sp>
    <p:nvSpPr>...
    <p:spPr>
      <a:xfrm>...
      <a:prstGeom prst="rect">...
      <a:grpFill/>
    </p:spPr>
    <p:style>...
    <p:txBody>...
  </p:sp>
</p:grpSp>
```



5.8.5 Line Properties

While it is obvious that line properties, a:ln are used to represent properties for lines, what may be less obvious is where this structure can appear. Lines aren't just for lines-- just about any object can have a line property-- usually referring to the outlines that are possible on shapes, pictures, or text. Lines used in this context also yield additional characteristics we wish to persist-- like what happens when line segments meet (i.e., line joins). So when understanding this section on line properties, it's important to visualize two possible cases-- a single line segment and the properties of that segment, and the case of multiple line segments (e.g., an outline of an autoshape). By considering both cases, the meaning of most properties becomes intuitively clear.

Line properties consist of several sections: line fill properties, line dash properties, line join properties, head/tail properties, as well as a few attributes.

5.8.5.1 Line Fill Properties

Line fill properties are a proper subset of general fill properties. One of the following can be used: noFill, solidFill, gradFill, or pattFill. Blip fills and group fills are not permitted for line fill properties.

5.8.5.2 Line Dash Properties

Line Dash properties may we either one of the presets, a:prstDash, or a custom dashing scheme, a:custDash. For the presets, the following options are available:

- solid: Solid (continuous) pen.
- dot: Dot style. [- - - - - - - - - - - -]
- dash: Short dash style. [---- ---- ---- ---- ---- ----]
- lgDash: Long dash style. [-------- -------- -------- --------]
- dashDot" Short dash followed by dot. [---- - ---- - ---- - ---- -]
- lgDashDot: Long dash followed by dot. [-------- - -------- - -------- -]
- lgDashDotDot: Long dash followed by two dots. [-------- - - -------- - -]
- sysDash: System short dash style (PS_DASH). [--- --- --- --- --- --- --- --- --- --- ---]
- sysDot: System dot style (PS_DOT). [-]
- sysDashDot: System short dash and one dot (PS_DASHDOT) [--- - --- - --- - --- - --- - --- - --- -]
- sysDashDotDot: System short dash and two dots (PS_DASHDOTDOT) [--- - - --- - - --- - - --- - - --- - - --- - -]

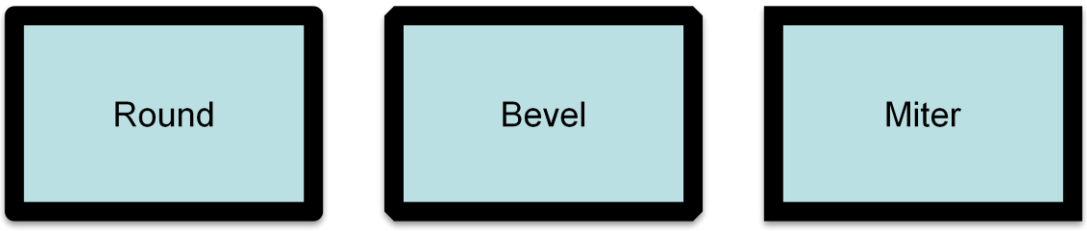
5.8.5.2.1 Custom Dashes

Custom dashes allow full flexibility in expressing any dashing scheme. Custom dashes are also known as dash stop lists, a:ds, due to the way the custom dashes are expressed. An element of the list specifies two attributes: d for the length of the dash relative to line width, and sp for length of the space relative to line width. Any number of elements may be combined into a dash stop list for full generality in expressing dashing schemes.

5.8.5.3 Line Join Properties

```
<a:ln w="38100" cap="sq" cmpd="thickThin" algn="ctr">
  <a:solidFill>
    <a:schemeClr val="lt1"/>
  </a:solidFill>
  <a:prstDash val="sysDot"/>
  <a:bevel/>
</a:ln>
```

Line join properties are for expressing the visual appearance of what happens when line segments meet. They can be round, beveled, or mitered. Notice the corners of the following rectangles, which illustrate the effect line join properties have.

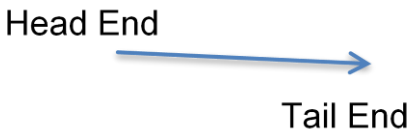


The only attribute of line join properties is lim. This attribute limits the amount by which lines can be extended to form a join. Normally, this is a relatively infrequent occurrence, but in the case of nearly parallel lines, this attribute comes into play.

5.8.5.4 Head/Tail End Properties

Head/Tail End properties specify whether there are any special attachments to the head or the tail of a line. All parameters are specified in attributes: a type, a w (width of line end to width of line), and a len (length of the end relative to the line width). By default, no head/tail end properties are applied. The type can be one of: none, triangle, stealth, diamond, oval, arrow. w and len can be one of sm, med and lg corresponding to small, medium, and large respectively.

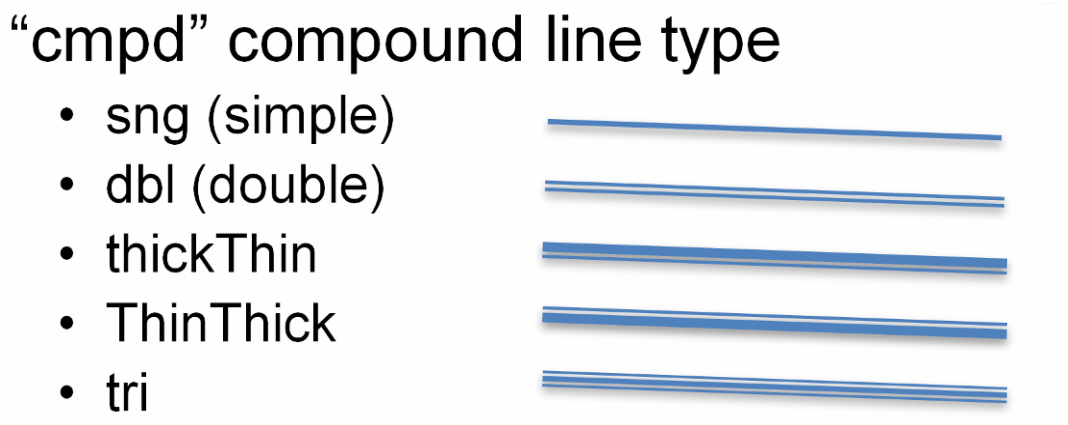
```
<a:ln w="25400" cap="rnd"
      cmpd="sng" algn="ctr">
  <a:solidFill>
    <a:srgbClr val="4F81BD"/>
  </a:solidFill>
  <a:prstDash val="solid"/>
  <a:tailEnd type="arrow" w="lg" len="lg"/>
</a:ln>
```



5.8.5.5 Line Attributes

Line Properties, a:ln, takes several attributes: w specifies the line width. cap specifies whether the line ends are round (value rnd), square (sq), or flat (flat).

cmpd specifies a compound line type. Its permitted values are shown below:



5.8.6 Effects

Effects are most naturally applied to shapes, but like fill properties and line properties, they can apply to shapes, pictures, and text. Effects are represented two ways: via an Effect List, a:effectLst, or an effects container, a:effectDag.

5.8.6.1 Effects Lists

```
<p:sp>
  <p:nvSpPr>...
  <p:spPr>
    <a:xfrm>...
    <a:prstGeom prst="star5">...
    <a:effectLst>
      <a:glow rad="190500">
        <a:schemeClr val="accent5">
          <a:alpha val="80000"/>
        </a:schemeClr>
      </a:glow>
      <a:outerShdw blurRad="50800" dist="50800"
                   dir="2700000" algn="tl"
                   rotWithShape="0">
        <a:srgbClr val="000000">
          <a:alpha val="43137"/>
        </a:srgbClr>
      </a:outerShdw>
      <a:reflection stA="75000" endA="10000"
                    dist="101600" dir="5400000"
                    sy="-100000" algn="bl"
                    rotWithShape="0"/>
      <a:softEdge rad="31750"/>
    </a:effectLst>
    <a:scene3d>...
    <a:sp3d>...
  </p:spPr>
  <p:style>...
  <p:txBody>...
</p:sp>
```

An effect list is made up of one or more primitive effects that can be applied one after another. The primitives are:

- Blur
- fillOverlay
- glow
- innerShdw
- outerShdw
- prstShdw
- reflection
- softEdge

5.8.6.2 Blur

Blur blurs all color channels, including alpha. Two attributes, rad (radius of blur) and grow (boolean), apply here. grow specifies if the bounds should grow as a result of the blurring.

5.8.6.3 Inner Shadow

```
<a:effectLst>
  <a:innerShdw blurRad="317500"
               dist="293171"
               dir="13500000">
    <a:srgbClr val="000000">
      <a:alpha val="43000"/>
    </a:srgbClr>
  </a:innerShdw>
</a:effectLst>
```

Inner Shadows contain a color choice, as well as three attributes:

- blurRad: blur radius
- dist: how far to offset the shadow
- dir: direction to offset the shadow

5.8.6.4 Outer Shadow

```
<a:effectLst>
  <a:outerShdw blurRad="50800" dist="50800"
               dir="2700000"
               sx="106000" sy="106000"
               algn="tl" rotWithShape="0">
    <a:srgbClr val="000000">
      <a:alpha val="43137"/>
    </a:srgbClr>
  </a:outerShdw>
</a:effectLst>
```

Outer shadows contain a color choice as well as several attributes:

- blurRad: blur radius
- dist: how far to offset the shadow
- dir: direction to offset the shadow
- sx, sy: horizontal/vertical scale factors
- kx, ky: horizontal/vertical skew angles

- algn: shadow alignment. Alignment happens first and effectively sets the origin for scale, skew, and offset
- rotWithShape: (boolean) Rotate shadow with shape

5.8.6.5 Preset Shadows

Preset shadows consist of a color choice, and a preset shadow:

shdw1
shdw2
shdw3
shdw4
shdw5
shdw6
shdw7
shdw8
shdw9
shdw10
shdw11
shdw12
shdw13
shdw14
shdw15
shdw16
shdw17
shdw18
shdw19
shdw20

The attributes for Preset Shadows are:

- dist: how far to offset the shadow
- dir: direction to offset the shadow

5.8.6.6 Reflection Effects

```
<a:effectLst>
  <a:reflection blurRad="12700" stA="50000" endPos="75000"
                dist="12700" dir="5400000" sy="-100000"
                algn="bl" rotWithShape="0"/>
</a:effectLst>
```

Reflections are represented entirely through attributes:

- blurRad: Blur Radius
- stA: (Start Alpha) starting reflection opacity
- stPos: start position along gradient ramp of start alpha value
- endA: (End Alpha) ending reflection opacity
- endPos: end position along gradient, ramp of end alpha value
- dist: how far to offset reflection
- dir: Direction to offset reflection
- fadeDir: direction of alpha gradient, ramp relative to shape itself
- sx, sy: horizontal/vertical scale factors
- kx, ky: horizontal/vertical skew angles
- algn: reflection alignment
- rotWithShape: (boolean)
- rotate: reflection with shape

5.8.6.7 Soft Edge Effects

```
<a:effectLst>
  <a:softEdge rad="127000"/>
</a:effectLst>
```

Soft Edge blurs the edges of the applied object subject to the specified blur radius rad.

5.8.6.8 Glow Effects

```
<a:effectLst>
  <a:glow rad="101600">
    <a:schemeClr val="accent2">
      <a:alpha val="60000"/>
    </a:schemeClr>
  </a:glow>
</a:effectLst>
```

A glow effect is very similar to a soft edge effect, but differs in that it permits a color specification in addition to rad. Basically, a glow is a soft edge effect, except with the color specified used instead of the object's color.

5.9 Shape Definitions and Attributes

5.9.1 Introduction

This document provides a high-level overview of the content described in the dml-shapeGeometry.xsd schema.

This aspect of DrawingML deals mainly with the shapes and their attributes, and is broken down into two topics:

- Working with preset shapes

- Defining custom shapes and their properties

5.9.2 The Coordinate Systems

To specify a shape there are a few high level systems that must first be understood, namely the coordinate systems that will be used. These are the document, shape and path coordinate systems, described in the following sub clauses.

5.9.2.1 The Document Coordinate System

To first specify a shape within a document the document coordinate system must be understood. This system has both an x and y component and starts with a value of (0,0) in the upper left corner of the document. As the x-coordinate increases, the point will move to the right. As the y-coordinate increases, the point will move downwards. The units of measurement within the document coordinate system are EMUs (91440 EMUs/U.S. inch, 36000 EMUs/cm). In addition to specifying a position for the shape, you must also specify the width and height of the shape, which is called the extent of the shape. This value is again measured in EMUs. To specify these two values, the following transform would be used.

```
<p:sp>
  <p:spPr>
    <a:xfrm>
      <a:off x="3200400" y="1600200"/>
      <a:ext cx="1200000" cy="1000000"/>
    </a:xfrm>
  </p:spPr>
</p:sp>
```

Here we can see that this new shape will be placed at x = 3200400 and y = 1600200 within the document coordinate system. In addition, we see that this shape will have a width of 1200000 EMUs and a height of 1000000 EMUs.

The width and height set the bounding box within which the entire shape will be contained.

5.9.2.2 The Shape Coordinate System

Now that we have a width and height specified, we can now move into the explanation of the shape coordinate system. The shape coordinate system has both an x and y component and starts with a value of (0,0) in the upper left corner of the shape. The width and height of this coordinate system are specified by the extent of the shape, which was recently specified above, and the units are once again EMUs. This coordinate system is used to define the locations of many of the shape attributes.

5.9.2.3 The Path Coordinate System

The final coordinate system is the path coordinate system which also has both an x and y component and starts with a value of (0,0) in the upper left corner of the shape. Now it must be known that this coordinate system is a unique one in that its units are relative to the specified width and height of the coordinate space. The path coordinate system has exactly the same EMU dimensions as the shape coordinate system but

different units. While the shape coordinate system uses EMUs, the path coordinate system uses (1/width) as the x units and (1/height) as the y units. That is if the path was specified to have a width of 2 and a height of 1, then the path coordinate (1,1) would be equivalent to (600000,1000000) in the shape coordinate system. The path coordinate system will be better understood later, once the path element is described.

Note that all dimensions and coordinates must be specified using whole numbers.

5.9.3 Specifying a Preset Shape

Within the Shape Definitions and Attributes section of DrawingML there are many pre-defined shapes that can be used, 187 to be exact. Of course, if the user does not wish to use a preset shape there is always the option of specifying a custom shape that will be described further in §5.9.4.

5.9.3.1 Defining a Preset Shape

It is quite easy to specify a preset shape as that is the whole notion around presets. They are meant to solve the most common cases of shape definition.

To specify a heart shape for instance the following DrawingML code can be used.

```
<p:sp>
  <p:spPr>
    <a:xfrm>
      <a:off x="1981200" y="533400"/>
      <a:ext cx="1143000" cy="1066800"/>
    </a:xfrm>
    <a:prstGeom prst="heart">
    </a:prstGeom>
  </p:spPr>
</p:sp>
```

This heart is rendered by the generating application using the custom shape code for this shape, which is fully documented within ST_ShapeTypes located in the reference documentation. Thus, we see that the user need on specify the preset name to place a shape within their document.

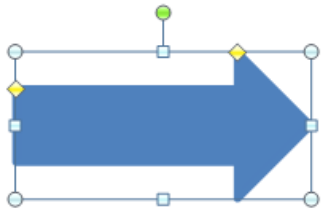
5.9.3.2 Adjusting a Preset Shape

While specifying a preset shape is convenient and looks good most of the time. There may also be the need for the user to adjust this preset to more closely suit the needs of their document. For this we introduce the notion of adjust values. The preset shape is built using lines, curves and calculations, just as a custom shape

would be defined. To allow for the adjusting of these preset shapes we have based certain properties of shapes on adjust values rather than concrete dimensions. This means that they can be modified which will in turn modify the geometry of the shape.

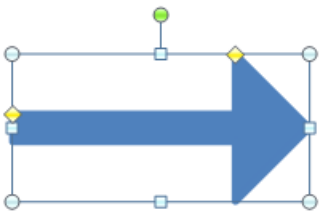
A simple arrow would be specified using the following DrawingML code.

```
<p:sp>
  <p:spPr>
    <a:xfrm>
      <a:off x="3276600" y="990600"/>
      <a:ext cx="978408" cy="484632"/>
    </a:xfrm>
    <a:prstGeom prst="rightArrow">
      <a:avLst>
        <a:gd name="adj1" fmla="val 50000"/>
        <a:gd name="adj2" fmla="val 50000"/>
      </a:avLst>
    </a:prstGeom>
  </p:spPr>
</p:sp>
```



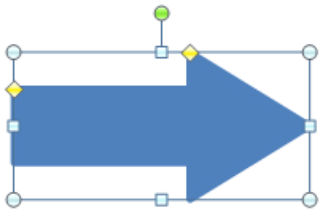
This will specify the basic arrow shown above which might be sufficient for the document needs of the user but it also may not. If this standard arrow is not sufficient then the two adjust values for this shape may be adjusted. For instance, if the body of the arrow is too large then the value for adj1 can be decreased. The following DrawingML code would specify such a case.

```
<a:gd name="adj1" fmla="val 18553"/>
```



Similarly, if the arrow head itself was too short then the value of adj2 can be increased. The following DrawingML code would specify such a case.

```
<a:gd name="adj2" fmla="val 81447"/>
```



Thus, it can be seen that while each preset is indeed a preset with a pre-defined geometry, it can be modified. Through the use of adjust values, the user is able to custom fit a preset shape to their document needs without having to specify an entirely custom shape.

Note that the values used here for adjust values have no real units as they are simply input parameters into the equations that make up the shape geometry. More on these equations and their parameters will be discussed in §5.9.4.2.

5.9.4 Specifying a Custom Shape

In addition to the specifying of a preset shape there is also the possibility of a specifying a custom shape. This is accomplished by defining a geometry from a set of construction methods and applying various shape properties to this geometry. This compliments preset shapes, giving the user the opportunity to specify a complete shape with any custom properties that are deemed necessary.

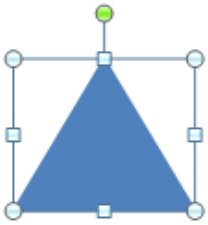
5.9.4.1 Defining the Geometry

Just like a preset shape, a custom shape has a position and a shape bounding box that is specified by the offset and extent transform values. The shape coordinate system is defined by these values as was described in section 1.2 above. The path coordinate system is also partially defined by these in that it has it's width and height set by these values. The units of the path system however are determined by the specified width and height of the path.

A custom shape with a single path can be specified using the following DrawingML code.

```
<p:sp>
  <p:spPr>
    <a:xfrm>
      <a:off x="3200400" y="1600200"/>
      <a:ext cx="1200000" cy="1000000"/>
    </a:xfrm>
    <a:custGeom>
      <a:pathLst>
        <a:path w="2" h="2">
          <a:moveTo>
            <a:pt x="0" y="2"/>
          </a:moveTo>
```

```
            <a:lnTo>
              <a:pt x="2" y="2"/>
            </a:lnTo>
            <a:lnTo>
              <a:pt x="1" y="0"/>
            </a:lnTo>
            <a:close/>
          </a:path>
        </a:pathLst>
      </a:custGeom>
    </p:spPr>
  </p:sp>
```



As can be seen in the above code, the path has a width and height of 2. This means that the path coordinate space will have units of (1/2 * shape width) for x-coordinate and (1/2 * shape height) for the y-coordinate. Thus we see that a coordinate of (2,2) in the path coordinate system will be the same as (1200000,1000000) within the shape coordinate system.

To define the shape path above we can see that there are a few different parts to defining this custom shape. The first is to define the first path in what is called the path list. It should be noted that the path list can have multiple paths in it, some filled, some not, some outlined, some not. To define the path we must specify the width, height and thus units for this path via the following DrawingML.

```
  <a:path w="2" h="2">
```

This sets up the path coordinate system for this path as was previously described. Next we need to move the drawing cursor to the point in this path coordinate system that we wish to start drawing our shape from. The following DrawingML does just that.

```
  <a:moveTo>
    <a:pt x="0" y="2"/>
  </a:moveTo>
```

This will move the drawing cursor to the bottom left position (0,2) which is equivalent to (0,1000000) in the shape coordinate system. Following this we can now start by drawing the first line in the shape via the following line.

```
<a:lnTo>
  <a:pt x="2" y="2"/>
</a:lnTo>
```

This will draw a line from the current drawing cursor position of (0,2) to (2,2) which is the bottom right corner of the path coordinate system. This is equivalent to drawing a line from (0,1000000) to (1200000,1000000) in the shape coordinate system. Now that we have the bottom edge of the triangle drawn we can continue to the final edge in the shape via the following.

```
<a:lnTo>
  <a:pt x="1" y="0"/>
</a:lnTo>
```

This will draw the final line that will be drawn from the current drawing cursor position of (2,2) to (1,0) which is in the top middle of the path coordinate system. This is equivalent to drawing a line from (1200000,1000000) to (600000,1000000) in the shape coordinate system. Now that most of the triangle has been drawn. It should be noted that since the <close/> element is specified at the end of the path that a line will be drawn from the last point in the path back to the first point in the path. This explains a bit of the existence of the following final element.

```
<a:close/>
```

This finalizes the edges of the shape path being specified. Since the fill of this path is set to normal, this path will have a fill no matter if this close tag is specified or not. However, the fact that it is specified determines that there will be a final edge drawn between the final drawing cursor point and the path starting point. Now that the path has been fully specified, this shape can be filled and thus be considered finished.

5.9.4.2 Adjusting the Geometry

Now that we have shown how a custom shape can be specified we can look at how it might be adjusted. This adjusting is different from the typical resizing that can happen by using the shape transform elements. Using these shape adjusting methods, a shape can be made to have many different resize/adjustment characteristics.

5.9.4.3 Geometry Guides

A guide within a shape is essentially an equation with a set number of inputs and a single output. A guide is used to calculate construction values for a shape and thus can be manipulated to govern the shape's overall geometry.

An example of this can be seen in the following DrawingML.

```
<gdLst>
  <gd name=”y1” fmla=”*/ h adj1 100”/>
</gdLst>
```

This guide will calculate it's output based on 3 input parameters and assign this output to a guide named y1. The formula that will be used in the calculation here is the multiply divide formula. The result for this guide will be calculated in the following manner: y1 = ((h * adj1) / 100). After the result here is calculated, the guide y1 can be used later within the <gdlst> or <path> to calculate further values. That is it can be used as an input for calculating another guide value. These guides then allow for a path to be based off of series of equations rather than static path coordinate values. To use a guide in the defining of a path we would simply specify the following within the path list.

```
<a:lnTo>
  <a:pt x="2" y="y1"/>
</a:lnTo>
```

This would draw a line to the point (2,y1) where y1 is the calculated result of the guide equation shown above. The drawing of this line will then change based on the input parameters of h and adj1 which are previously calculated guides as well.

Note that while h is a previously calculated guide. It is not calculated for each shape, rather it is a built-in guide that the generating application makes available to the shape.

5.9.4.3.1 Adjust Handles

To allow for the adjusting UI of a shape we introduce the notion of an adjust handle. This adjust handle will be linked to adjust values that will then be used as input to the guide equations defined previously. The numerical chain described here will thus directly change the geometry of the related shape. There are two types of adjust handles that can be specified. An XY adjust handle acts in the horizontal/vertical direction and has two related guides, both a horizontal and a vertical respectively. A polar adjust handle acts in a polar manner and has two related guides as well. One guide for the radial width and the other for the radial angle. An adjust handle is specified to have an x and y coordinate as well as these adjust handles. This adjust handle can then be moved around in a generating application's UI to adjust a pair of guides which will in turn adjust the shape being rendered.

An adjust handle can be specified by the following DrawingML.

```
<ahXY gdRefX="adj1" minX="-2147483647" maxX="2147483647" gdRefY="adj2"
  minY="-2147483647" maxY="2147483647">
  <pos x=”x1” y=”y1”/>
</ahXY>
```

Above is an XY adjust handle that has two guide references, a min and max allowed position for both the x and y coordinates as well as a position within the shape coordinate system where this adjust handle should be placed.

5.9.4.4 Additional Properties

In addition to specifying the geometry for a shape and all the associated adjustments for it there are also a few other properties that are of special significance. These properties do not act on the geometry of the shape but instead enhance a shape so that it may be used for a more specialized task.

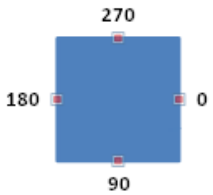
5.9.4.4.1 Connection Sites

As one may have experienced when trying to draw a diagram with shapes and connections between those shapes, it is quite difficult to move a part of your diagram without entirely redrawing the connections between shapes. For this, there is the notion of connection sites that allow for the specification of specific points within a shape to attach connection shapes to. This allows a user to build a diagram from a set of shapes and connect them together using connection shapes. A connection site is specified within the connection list and consists of an x-coordinate, y-coordinate and an attachment angle.

The following DrawingML code defines two connection sites, one at each edge of this triangle.

```
<a:cxnLst>
  <a:cxn ang="10800000">
    <a:pos x="0" y="679622"/>
  </a:cxn>
  <a:cxn ang="0">
    <a:pos x="1705233" y="679622"/>
  </a:cxn>
</a:cxnLst>
```

The attachment angle works by specifying an angle in 60,000ths of a degree that a connector should attach to. The diagram below shows an actual connection point and the attachment angles that correspond to the sides of this point. This information along with the geometry of the shape is used by the generating applications connector routing algorithm to correctly route connectors around connected shapes.



5.9.4.4.2 Text Rectangle

Within each shape is a text box that allows for the attaching of text to any given shape. The text rectangle defines where text will reside within the shape. Depending on Auto-fit options that are selected for the body

of text attached to this shape the text may intentionally flow outside this text rectangle. It must also be pointed out that this text rectangle will also be the bounding box that is used to compute the geometry of a <prstTxWarp>. The EMU dimensions of this text rectangle will be used to compute this geometry just like the transform extent element is used to compute the actual shape.

The following DrawingML specifies a text rectangle within a shape.

```
<a:rect l="0" t="0" r="1200000" b="1000000"/>
```

The text rectangle shown above will have a left edge of 0 x-coordinate, top edge of 0 y-coordinate, right edge of 1200000 x-coordinate and a bottom edge of 1000000 y-coordinate. This will effectively specify a space that is 1200000 EMUs in width and 1000000 EMUs in height.

Note that the edges of this text rectangle can be set so as to allow text to be placed outside the actual geometry of the shape.

5.10 Pictures

5.10.1 Introduction

This subclause provides a high-level overview of the content described in the dml-picture.xsd schema.

The DrawingML Picture file format is broken down into the following subjects:

- Specifying a basic picture
- Attaching properties to this picture
- Transforming this picture

The best way to understand the above subjects will be to cover them in the ordering above.

5.10.2 Specifying a Basic Picture

A picture can be inserted into a presentation slide by use of the picture element, pic, which is similar to the shape element but contains some key differences that enable more complete storage of picture information. This basic picture element should contain a blipfill and some basic non-visual picture properties.

```
<p:pic>
  <p:nvPicPr>
    <p:cNvPr id="4" name="St_Patrick's_Day.jpg"/>
    <p:cNvPicPr>
      <a:picLocks noChangeAspect="1"/>
    </p:cNvPicPr>
    <p:nvPr/>
  </p:nvPicPr>
  <p:blipFill>
    <a:blip r:embed="rId2"/>
    <a:stretch>
      <a:fillRect/>
    </a:stretch>
  </p:blipFill>
  <p:spPr>
    <a:xfrm>
      <a:off x="1346200" y="914400"/>
      <a:ext cx="3657600" cy="2743200"/>
    </a:xfrm>
    <a:prstGeom prst="rect">
      <a:avLst/>
    </a:prstGeom>
    <a:noFill/>
    <a:ln>
      <a:noFill/>
    </a:ln>
  </p:spPr>
</p:pic>
```

5.10.3 Attaching Properties to this Picture

Now that the base picture has been specified, we can move on to more complicated properties, such as recolor options and picture descriptions. In the picture below, notice that the picture that was once green has been re-colored in a purple hue. This can be done by utilizing the duotone element, which allows for the setting of two base colors to use for re-coloring the entire picture. The first is used to act upon the darker regions of the picture and the second is used to act upon the lighter regions. This we can see below that black (#000000) is indeed used below for the darker regions while accent4 (purple in this case) is used for the lighter areas.

```
<p:pic>
  <p:nvPicPr>
    <p:cNvPr id="4" name="St_Patrick's_Day.jpg"
      descr="This is a Saint Patrick's day picture"/>
    <p:cNvPicPr>
      <a:picLocks noChangeAspect="1"/>
    </p:cNvPicPr>
    <p:nvPr/>
  </p:nvPicPr>
  <p:blipFill>
    <a:blip r:embed="rId2">
      <a:duotone>
        <a:srgbClr val="000000"/>
        <a:schemeClr val="accent4"/>
      </a:duotone>
    </a:blip>
    <a:stretch>
      <a:fillRect/>
    </a:stretch>
  </p:blipFill>
```

```
    <p:spPr>
      <a:xfrm>
        <a:off x="1346200" y="914400"/>
        <a:ext cx="3657600" cy="2743200"/>
      </a:xfrm>
      <a:prstGeom prst="rect">
        <a:avLst/>
      </a:prstGeom>
      <a:noFill/>
      <a:ln>
        <a:noFill/>
      </a:ln>
    </p:spPr>
  </p:pic>
```

5.10.4 Transforming this Picture

Now that both basic properties and additional picture properties have been specified, we can begin incorporating shape properties. Below is the same picture as described above, with 3D camera perspective applied along with a simple shadow and a white outline. These shape properties are the same that can be applied to a shape element. One picture-specific difference can be seen here with the border around the picture. Instead of the border growing both inward and outward, it only grows outward.

```
  <p:pic>
    <p:nvPicPr>
      <p:cNvPr id="4" name="St_Patrick's_Day.jpg"
        descr="This is a Saint Patrick's day picture"/>
      <p:cNvPicPr>
        <a:picLocks noChangeAspect="1"/>
      </p:cNvPicPr>
      <p:nvPr/>
    </p:nvPicPr>
```

```
      <p:blipFill>
        <a:blip r:embed="rId2">
          <a:duotone>
            <a:srgbClr val="000000"/>
            <a:schemeClr val="accent4"/>
          </a:duotone>
        </a:blip>
        <a:stretch>
          <a:fillRect/>
        </a:stretch>
      </p:blipFill>
      <p:spPr>
        <a:xfrm>
          <a:off x="1346200" y="914400"/>
          <a:ext cx="3657600" cy="2743200"/>
        </a:xfrm>
        <a:prstGeom prst="rect">
          <a:avLst/>
        </a:prstGeom>
        <a:noFill/>
        <a:ln w="57150">
          <a:solidFill>
          <a:schemeClr val="bg1"/>
          </a:solidFill>
        </a:ln>
        <a:effectLst>
          <a:outerShdw blurRad="50800" dist="50800" dir="2700000" algn="tl"
            rotWithShape="0">
            <a:srgbClr val="7D7D7D">
              <a:alpha val="65000"/>
            </a:srgbClr>
          </a:outerShdw>
        </a:effectLst>
        <a:scene3d>
          <a:camera prst="perspectiveRelaxedModerately"/>
          <a:lightRig rig="threePt" dir="t">
            <a:rot lat="0" lon="0" rev="18900000"/>
          </a:lightRig>
        </a:scene3d>
      </p:spPr>
    </p:pic>
```

End of informative text.

5.11 WordprocessingML Drawing

Within a WordprocessingML document, it is possible to include graphical DrawingML objects:

- Charts
- Diagrams
- Locked Canvases
- Pictures

When these objects are present in a word processing document, it is necessary to include information that specifies how the objects are to be positioned relative to the paginated document.

The WordprocessingML Drawing namespace acts in this capacity, specifying all information necessary to anchor and display DrawingML objects within a word processing document.

Consider a DrawingML picture that is to displayed in the center of the printed page on which it appears, modifying the flow of text as necessary. This object would be specified as follows:

```
<w:r>
  <w:drawing>
    <wp:anchor relativeHeight="10" allowOverlap="true">
      <wp:positionH relativeFrom="margin">
        <wp:align>center</wp:align>
      </wp:positionH>
      <wp:positionV relativeFrom="margin">
        <wp:align>center</wp:align>
      </wp:positionV>
      <wp:extent cx="2441542" cy="1828800"/>
      <wp:wrapSquare wrapText="bothSides"/>
      <a:graphic>
        …
      </a:graphic>
    </wp:anchor>
  </w:drawing>
</w:r>
```

The anchor element specifies that this object is not positioned in-line with text, and its child elements specify that the object is centered on the page horizontally and vertically, and that text can wrap around it in a square.

5.11.1 Object Anchoring

When the WordprocessingML Drawing namespace is used to anchor a DrawingML object within a document, that object can be anchored in one of two ways:

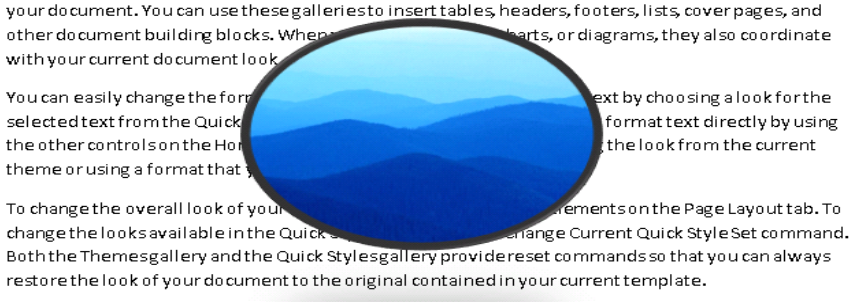
- In line with text - The object is displayed within the regular text stream (modifying line height and so on to accommodate it).

- Floating – The object is positioned absolutely or relatively within the document and text flow is modified as needed around it.

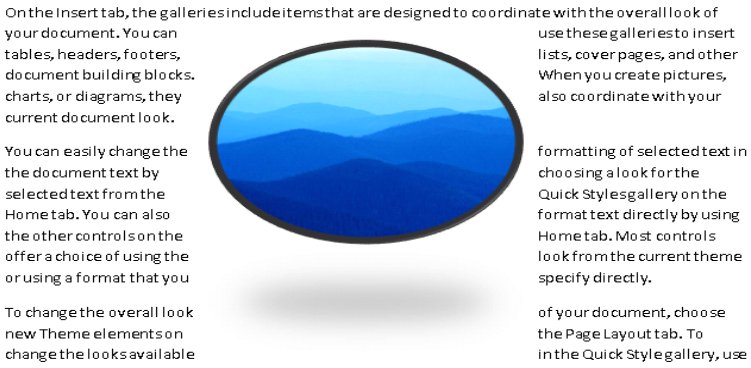
5.11.2 Text Wrapping

Aside from positioning data, WordprocessingML Drawing also needs to specify how text flows around the object. There are five different types of text wrapping which can be applied to floating objects present in WordprocessingML documents:

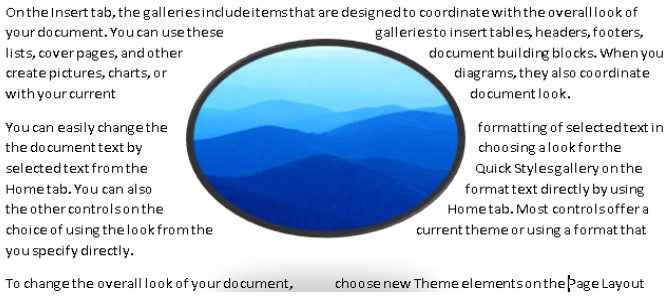
- In Front/Behind Text - In this type of text wrapping, the drawing object is positioned on the document and text is not displaced around it.



- Square Wrapping - In this type of text wrapping, the drawing object is positioned on the document and a rectangle is stored within the file format to determine the wrapping extents.



- Tight Wrapping - In this type of text wrapping, a wrapping polygon is created and stored in the WordprocessingML document, and this polygon determines how text wraps around the left and right sides of the drawing object.



- Through Wrapping - In this type of text wrapping, a wrapping polygon is created just like with tight wrapping, but any indents in the wrap polygon can be filled with text in this case.

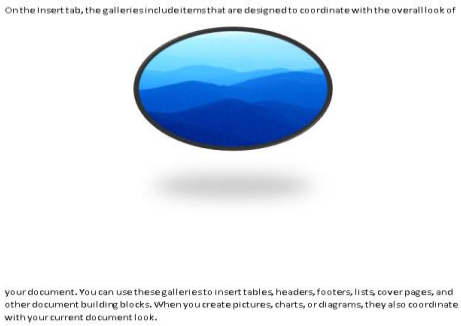
  If the wrapping polygon looks like the following:

  Tight wrapping would look like this:

  While through wrapping would look like this:

  In the latter case, notice that text fills in the 'indentation' within the wrapping polygon.

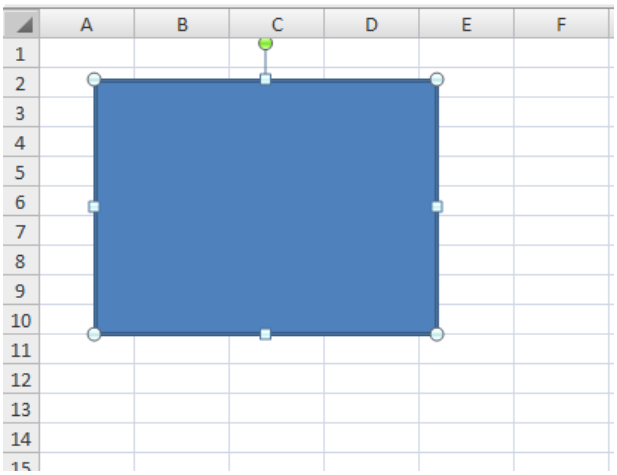
- Top and Bottom Wrapping - In this type of text wrapping, text cannot wrap around either side of the object, and shall only restart below the bottom edge of the document.



5.12 SpreadsheetML Drawing

5.12.1 Introduction

This subclause provides a high-level overview of the content described in the dml-spreadsheetDrawing.xsd schema. The elements in this schema specify how drawing elements are to be described within a spreadsheet. For example, suppose we want to specify a rectangle drawing shape within a worksheet to look like the following:



5.12.2 Overview

The elements that specify the drawing objects within a worksheet are all located within its respective drawing XML file. This file is located under the "drawings" folder inside the spreadsheet file. For example, if the drawing element is located on Worksheet 1, then the specifications for the said element would be located in the file \xl\drawings\drawing1.xml.

5.12.3 Worksheet Drawings

Within the drawing*.xml file is contained a single worksheet drawing wsDr element, which is the parent element for all the drawing elements. Its child specifies the anchoring properties of the drawing elements. It is

within this element that the main specifications for the drawing elements are located. For example in the above screenshot with a simple shape located on the worksheet, the XML for this would look like:

```
<xdr:wsDr>
  <xdr:absoluteAnchor>
    <xdr:pos x="2162175" y="1743075"/>
    <xdr:ext cx="1238250" cy="1314450"/>
    …
    </xdr:sp>
  </xdr:absoluteAnchor>
</xdr:wsDr>
```

In this SpreadsheetDrawingML code there is a single drawing specified almost exactly as it would within the regular DrawingML framework. However the SpreadsheetDrawingML wrapper that is used allows for the specifying of spreadsheet specific properties in addition to the normal drawing properties.

5.12.3.1 Anchoring Types

To define a drawing within a spreadsheet an anchoring type must be chosen. There are three different anchoring types allowed for use within a spreadsheet: Absolute Anchoring, One Cell Anchoring, and Two Cell Anchoring. Each of these types is described in the following subclauses.

5.12.3.1.1 Absolute Anchoring

Absolute Anchoring describes the placement of the drawing within the spreadsheet based upon absolute coordinates. This positioning information includes both position coordinates and extent coordinates. The absoluteAnchor element is what specifies this anchoring behavior and a sample usage is shown below.

```
<xdr:absoluteAnchor>
  <xdr:pos x="2162175" y="1552575"/>
  <xdr:ext cx="1238250" cy="1123950"/>
  …
  </xdr:sp>
</xdr:absoluteAnchor>
```

In this example, there is a single shape specified using absolute anchoring as its anchoring method.

5.12.3.1.2 One Cell Anchoring

One Cell Anchoring describes the placement of the drawing within the spreadsheet based upon offsets as well as a specified column and row. The offset is always in reference to the specified anchor cell and acts to offset the shape object from being exactly on top of the anchor cell. The offset information determines the actual placement of the drawing within the spreadsheet while the row and column are used to specify to which cell the drawing should be anchored. Thus, if the anchor cell changes positions then the drawing can be moved as well. The oneCellAnchor element is what specifies this anchoring behavior and a sample usage is shown below.

```
<xdr:oneCellAnchor>
  <xdr:from>
    <xdr:col>3</xdr:col>
    <xdr:colOff>333375</xdr:colOff>
    <xdr:row>8</xdr:row>
    <xdr:rowOff>28575</xdr:rowOff>
  </xdr:from>
  <xdr:ext cx="1238250" cy="1123950"/>
  …
  </xdr:sp>
</xdr:oneCellAnchor>
```

In this example, there is a single shape specified using one cell anchoring as its anchoring method.

5.12.3.1.3 Two Cell Anchoring

Two Cell Anchoring describes the placement of the drawing within the spreadsheet based upon offsets as well as a specified columns and rows. The offset is always in reference to the specified anchor cell and acts to offset the shape object from being exactly on top of the anchor cell. The offset information determines the actual placement of the drawing within the spreadsheet while the rows and columns are used to specify the cells to which the drawing should be anchored and upon which the resized is based. For instance, if the anchor cell changes positions then the drawing can be moved. Likewise, if the anchor cells behind the shape grow, then the shape can grow as well. The twoCellAnchor element is what specifies this anchoring behavior and a sample usage is shown below.

```
<xdr:twoCellAnchor>
  <xdr:from>
    <xdr:col>3</xdr:col>
    <xdr:colOff>447675</xdr:colOff>
    <xdr:row>8</xdr:row>
    <xdr:rowOff>28575</xdr:rowOff>
  </xdr:from>
  <xdr:to>
    <xdr:col>5</xdr:col>
    <xdr:colOff>466725</xdr:colOff>
    <xdr:row>14</xdr:row>
    <xdr:rowOff>9525</xdr:rowOff>
  </xdr:to>
  …
  </xdr:sp>
</xdr:twoCellAnchor>
```

In this example, there is a single shape specified using two cell anchoring as its anchoring method.

5.13 Charts

5.13.1 Overview

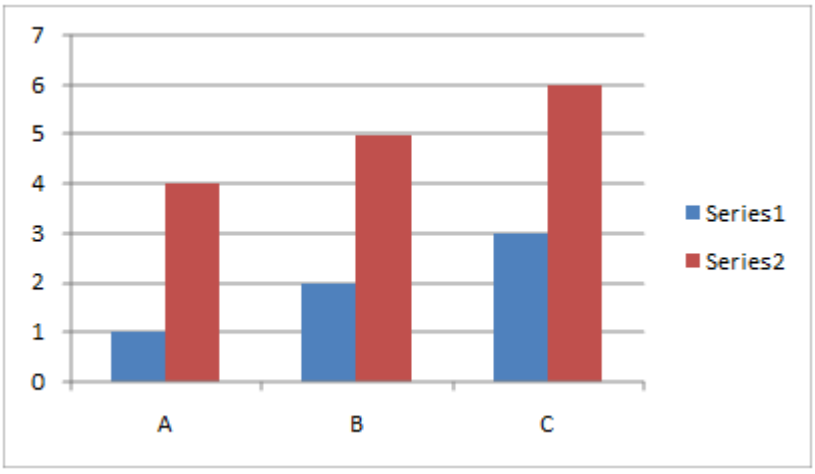
Charts provide a great way to visualize information by displaying a graphical representation of the data. The chart XML files can be reused and shared among different applications, such as a spreadsheet, presentation, and word processing.

Charts come in many different types and flavors, and this document provides a basic overview of both the different types of charts as well as the XML that is used to generate them.

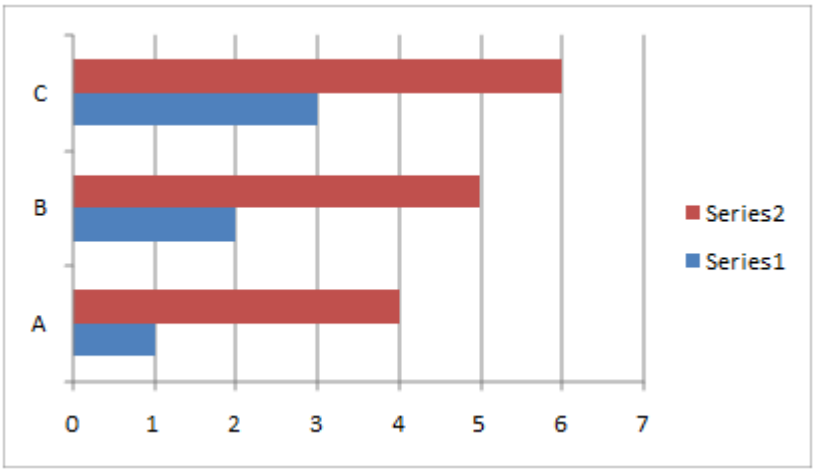
Applications may allow many different runtime behaviors for charts, such as rules for displaying them. This clause and its corresponding reference material define only the XML that is needed to store and generate the charts, and do not dictate any runtime behaviors.

5.13.1.1 Basic Chart Types

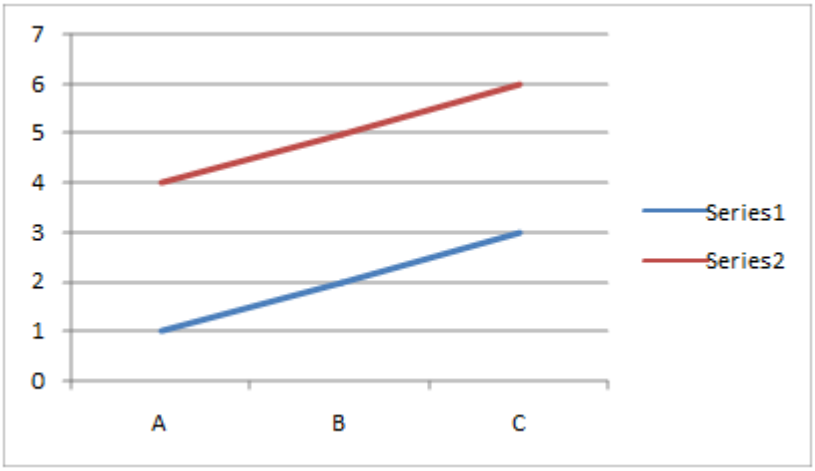
There are 10 basic chart types. Below are examples of each basic type:



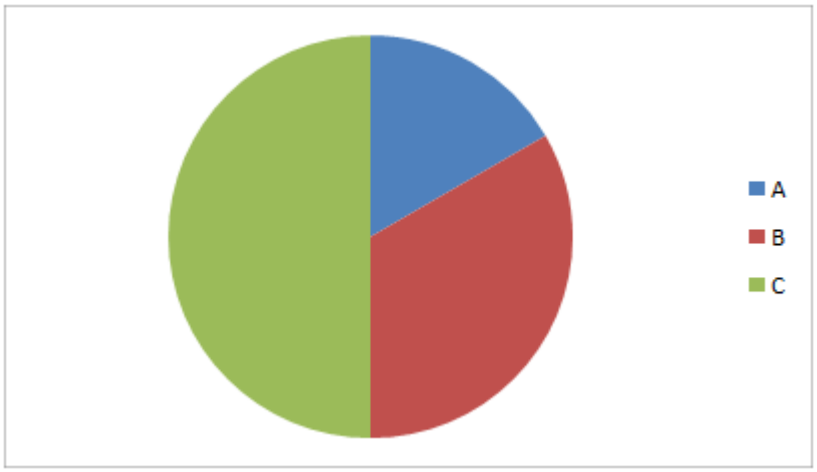
Column Chart (shown above)



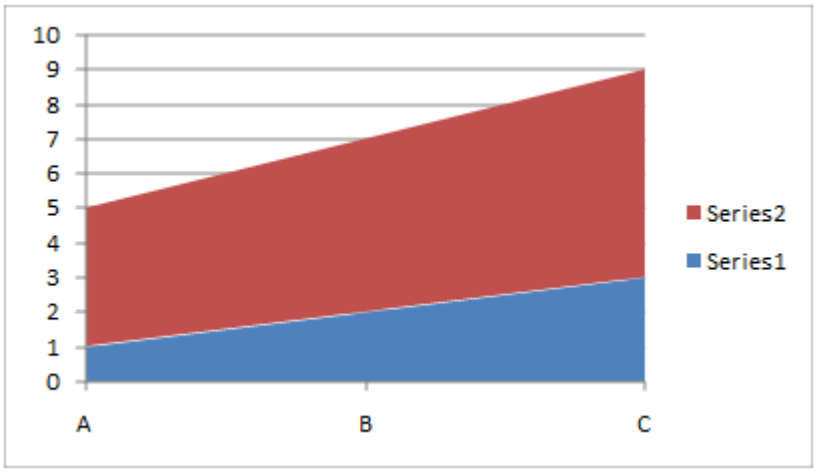
Bar Chart (shown above)



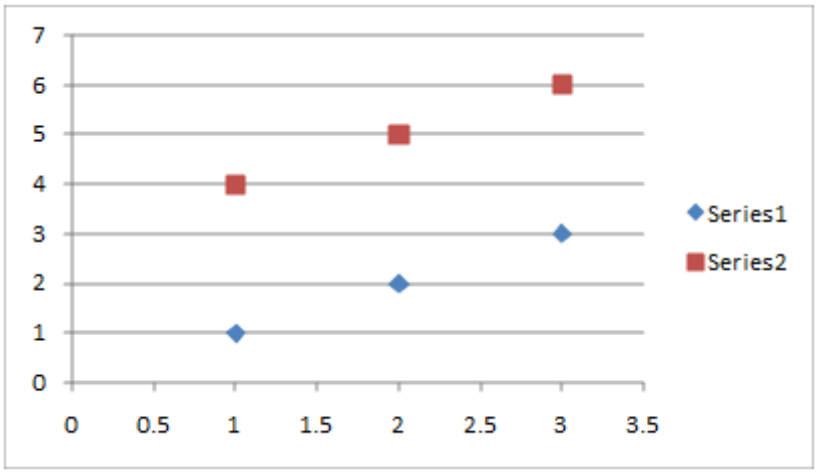
Line Chart (shown above)



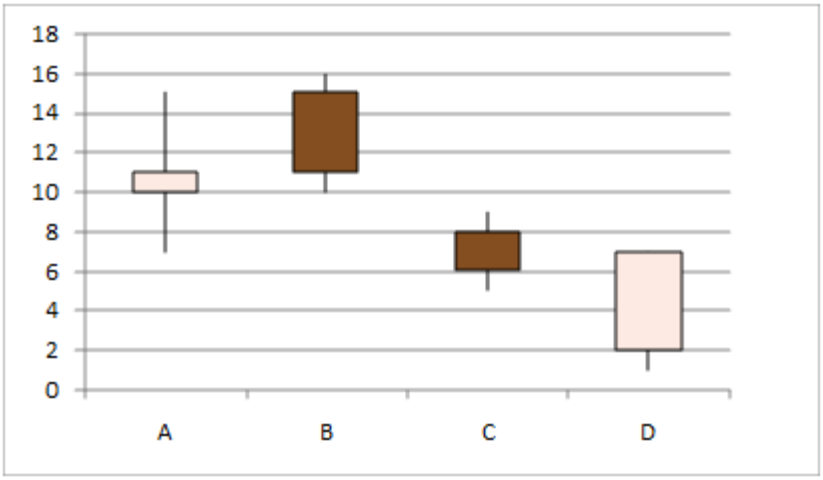
Pie Chart (shown above)



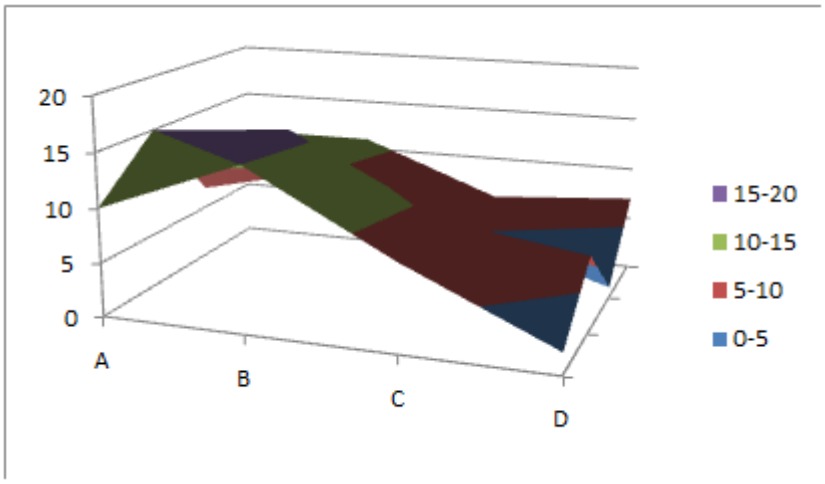
Area Chart (shown above)



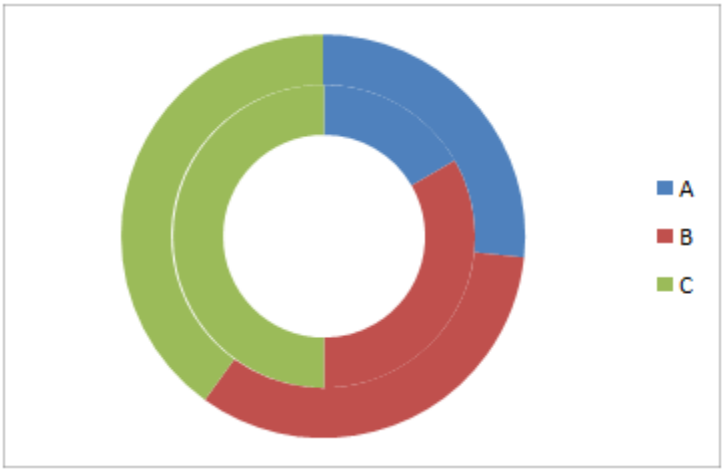
Scatter Chart (shown above)



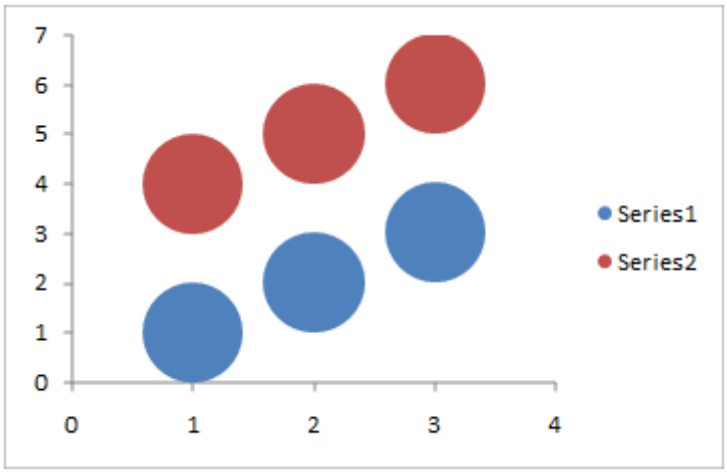
Stock Chart (shown above)



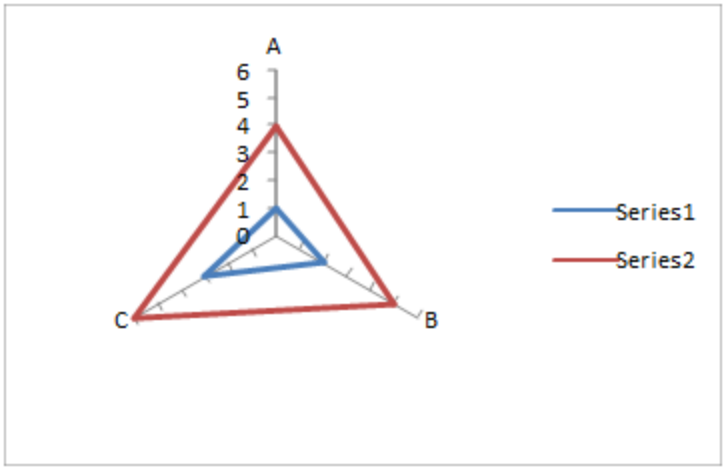
Surface Chart (shown above)



Doughnut Chart (shown above)



Bubble Chart (shown above)



Radar Chart (shown above)

5.13.1.2 Basic Chart Components

Here are some diagrams that label the different individual components of a chart. Some chart components, such as drop lines, are only shown on certain types of charts.

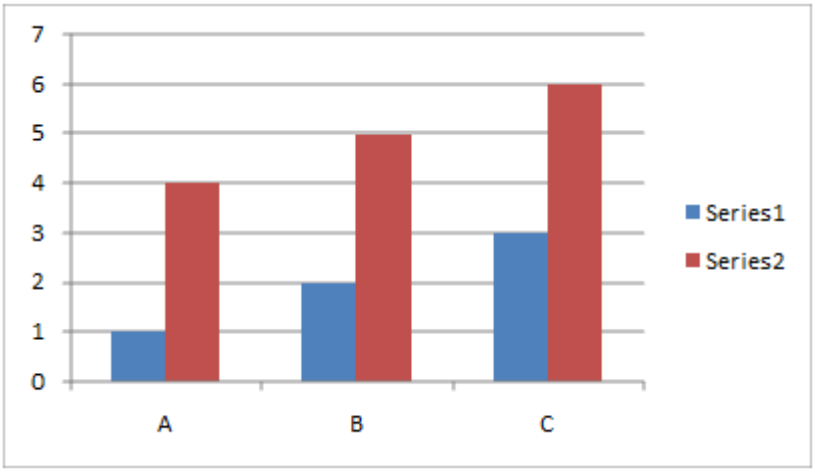
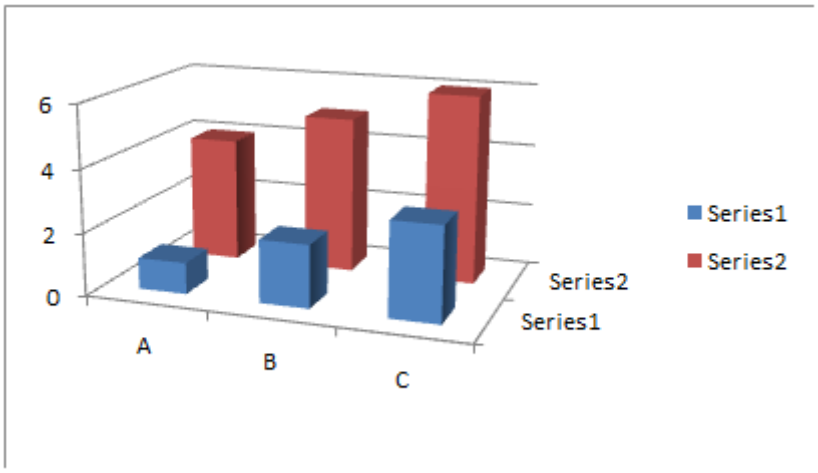
5.13.1.3 3D Charts

Most chart types also have three-dimensional representations. 3D charts have extra properties to describe depth, floor, or walls, as well as some other rendering effects. Below is a 2D column chart shown with its 3D counterpart.

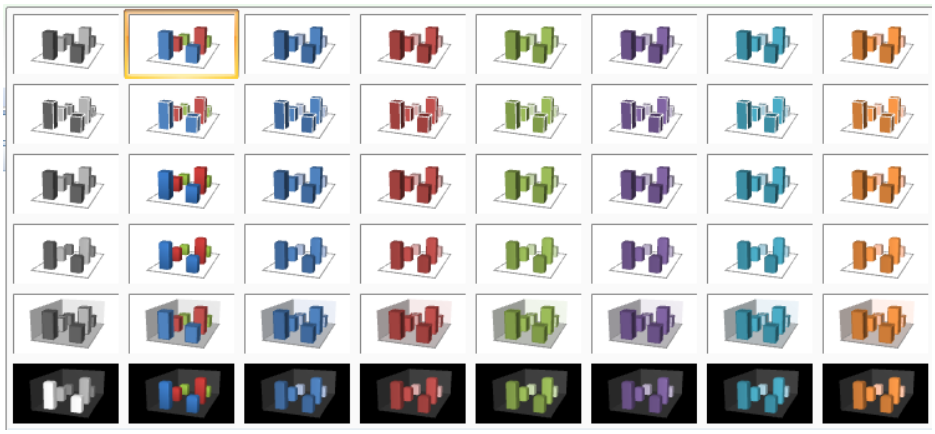




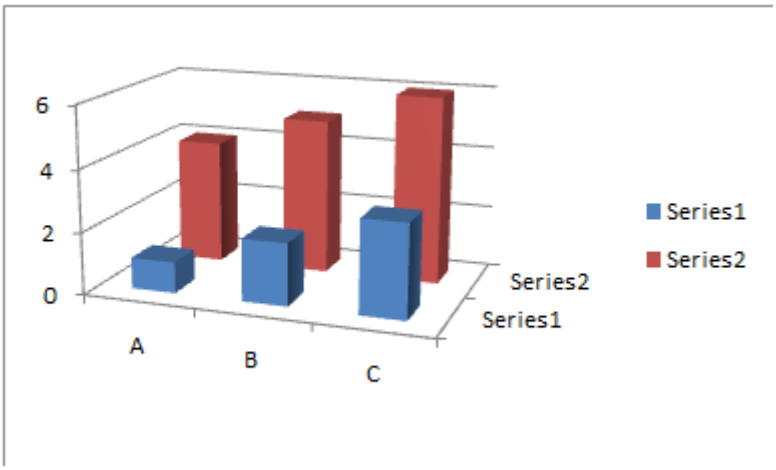
5.13.1.4 Chart Styles

Charts may have different styles applied to them. This is essentially just a coordinated set of coloring and formatting that is applied across an entire chart and all its elements. Styles allow a quick and easy way to coordinate the look and feel of a chart with the rest of the document. Below is a rendering of a column chart and pie chart showing the same data, with the same style applied. There is also a shot of many different types of styles. It is shown for both charts to illustrate how the idea of a style can apply, and be consistent, across different chart types.

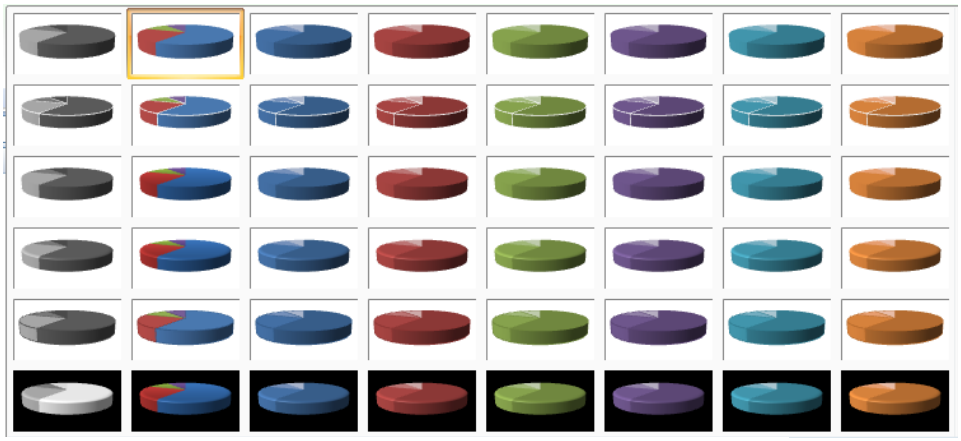
1

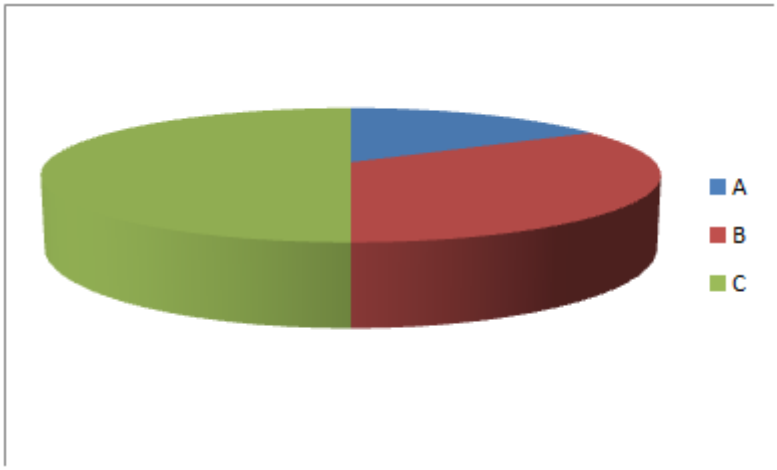


2



3





5.13.2 XML Overview

5.13.2.1 Relationships

A Drawing XML part contains a chart element, which expresses a relationship ID. This ID is referenced by the drawing.rels part, which points to the corresponding chart XML part. Chart XML contains the core definition of the chart.

5.13.2.2 Chart

Different chart types can have many different components defined in the XML, and not all are shown here. For many charts though, at a very high level, the chart XML is composed of the following pieces:

```
<chartSpace>
  <chart>
    <view3D>
    <plotArea>
      <layOut>
      <barChart>
        <cat>
        <val>
      <catAx>
      <valAx>
    </plotArea>
    <legend>
  </chart>
  <printSettings>
</chartSpace>
```

chartSpace is the root node, which contains an element defining the chart, and an element defining the print settings for the chart.

chart is the root element for the chart. If the chart is a 3D chart, then a view3D element is contained, which specifies the 3D view. It then has a plot area, which defines a layout and contains an element that corresponds to, and defines, the type of chart.

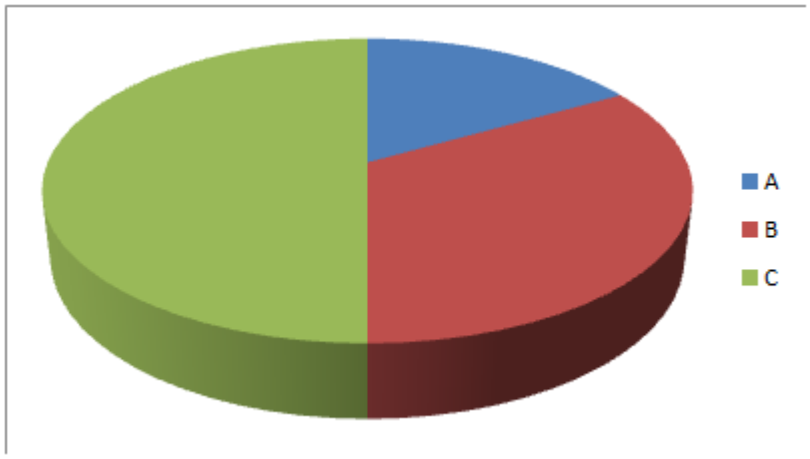
The element that defines the type of chart, barChart in this case, also specify caches for both category axis data (which is really just strings for the categories), as well as the for the numbers, or values, shown on the chart. The cat element defines the string cache for the category axis, and the val element defines the number caches.

Depending on the type of the chart, the plot area may optionally contain elements that define the axes—such as the value axis and category axis—or shape properties. In the example above, the category axis, catAx, and value axis, valAx are defined. These define things like positioning, orientation, label position, and tick marks for the axis. The actual strings and data that the axis corresponds to are defined by the cat and val elements.

Lastly, the chart element contains a legend element which defines the chart legend.

5.13.3 Example

The XML in this clause defines the following 3D chart:



For this example, the xml for the chart element will be shown in detail. The xml for the chart element follows:

```
<c:chart>
  <c:view3D>
    <c:rotX val="30"/>
    <c:perspective val="30"/>
  </c:view3D>
  <c:plotArea>
    <c:layout>
      <c:lastLayoutOuter>
        <c:x val="4.5"/>
        <c:y val="4.5"/>
        <c:w val="324.75"/>
        <c:h val="206.25"/>
      </c:lastLayoutOuter>
      <c:lastLayout>
        <c:x val="10.5"/>
        <c:y val="10.5"/>
        <c:w val="312.75"/>
        <c:h val="194.25"/>
      </c:lastLayout>
    </c:layout>
```

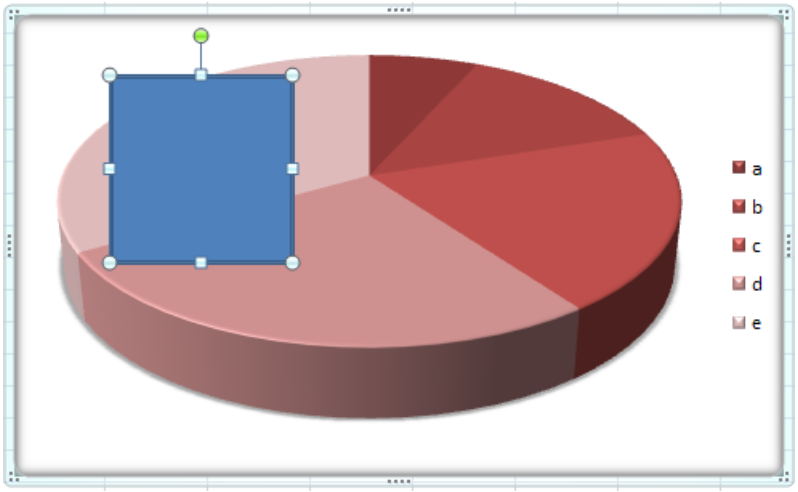
```
<c:pie3DChart>
  <c:varyColors val="1"/>
  <c:ser>
    <c:idx val="0"/>
    <c:order val="0"/>
    <c:cat>
      <c:strRef>
        <c:f>Sheet1!$A$1:$C$1</c:f>
        <c:strCache>
          <c:pt idx="0">
            <c:v>A</c:v>
          </c:pt>
          <c:pt idx="1">
            <c:v>B</c:v>
          </c:pt>
          <c:pt idx="2">
            <c:v>C</c:v>
          </c:pt>
        </c:strCache>
      </c:strRef>
    </c:cat>
    <c:val>
      <c:numRef>
        <c:f>Sheet1!$A$2:$C$2</c:f>
        <c:numCache>
          <c:pt idx="0">
            <c:v>1</c:v>
          </c:pt>
          <c:pt idx="1">
            <c:v>2</c:v>
          </c:pt>
          <c:pt idx="2">
            <c:v>3</c:v>
          </c:pt>
        </c:numCache>
      </c:numRef>
    </c:val>
  </c:ser>
</c:pie3DChart>
```

```
        <c:spPr>
          <a:noFill/>
          <a:ln w="25400">
            <a:noFill/>
          </a:ln>
        </c:spPr>
      </c:plotArea>
      <c:legend>
        <c:legendPos val="r"/>
        <c:layout>
          <c:lastLayout>
            <c:x val="333.75"/>
            <c:y val="81.75"/>
            <c:w val="19.5"/>
            <c:h val="51.75"/>
          </c:lastLayout>
        </c:layout>
      </c:legend>
      <c:plotVisOnly val="1"/>
    </c:chart>
```

5.14 Chart Drawing

5.14.1 Introduction

This subclause provides a high-level overview of the content described in the dml-chartDrawing.xsd schema. The elements in this schema specify how drawing elements are to be described within a chart. For example, suppose we want to specify a rectangle drawing shape within a chart to look like the following:



5.14.2 Overview

The elements that specify the drawing objects within a chart are all located within its respective drawing XML file. This file is located under the "drawings" folder inside the spreadsheet file.

5.14.3 Chart Drawings

Within the drawing*.xml file there is a single drawing file that contains the userShapes element. This element is the parent element for all the drawing elements within a single chart. Its child specifies the anchoring properties of the drawing elements. It is within this element that the main specifications for the drawing elements are located. For example in the above screenshot with a simple shape located in the chart, the XML for this would look like:

```
<c:userShapes>
  <cdr:relSizeAnchor>
    <cdr:from>
      <cdr:x>0.125</cdr:x>
      <cdr:y>0.13194</cdr:y>
    </cdr:from>
    <cdr:to>
      <cdr:x>0.36042</cdr:x>
      <cdr:y>0.53472</cdr:y>
    </cdr:to>
      …
    </cdr:sp>
  </cdr:relSizeAnchor>
</c:userShapes>
```

In the ChartDrawingML code above, there is a single drawing specified almost exactly as it would within the regular DrawingML framework. However, the ChartDrawingML wrapper that is used allows for the specifying of chart specific properties in addition to the normal drawing properties. The most interesting of these are the two anchoring types that define the placement behavior of a drawing within a chart.

5.14.3.1 Anchoring Types

To define a drawing within a chart an anchoring type must be chosen. There are two different anchoring types allowed for use within a chart: Absolute Anchoring and Relative Anchoring. These two types are described in the following two subclauses.

5.14.3.1.1 Absolute Size Anchoring

Absolute Anchoring describes the placement of the drawing within the chart based upon absolute chart coordinates. The absSizeAnchor element specifies anchoring behavior, using percentage-based position coordinates for the anchor location and extent coordinates (in EMUs) for drawing objects, as shown in the example below.<cdr:absSizeAnchor>

```
 <cdr:from>
  <cdr:x>0.125</cdr:x>
```

```
  <cdr:y>0.13194</cdr:y>
 </cdr:from>

    <cdr:ext cx="1238250" cy="1123950"/>
    …
    </cdr:sp>
  </cdr:absSizeAnchor>
```

In this example, there is a single shape specified using absolute anchoring as its anchoring method.

5.14.3.1.2 Relative Size Anchoring

Relative Anchoring describes the placement of the drawing within the chart based upon relative chart coordinates. For instance, if the chart increases in size then the shape will grow as well. This positioning information includes from and to elements which specify a percentage-based coordinate within the chart bounding box. The relSizeAnchor element is what specifies this anchoring behavior and a sample usage is shown below.

```
  <cdr:relSizeAnchor>
    <cdr:from>
      <cdr:x>0.125</cdr:x>
      <cdr:y>0.13194</cdr:y>
    </cdr:from>
    <cdr:to>
      <cdr:x>0.36042</cdr:x>
      <cdr:y>0.53472</cdr:y>
    </cdr:to>
      …
    </cdr:sp>
  </cdr:relSizeAnchor>
```

In this example, there is a single shape specified using relative anchoring as its anchoring method.

5.15 Diagrams

5.15.1 Introduction

This clause provides a high-level overview of the content described in the following schemas: dml-diagramTypes.xsd, dml-diagramDataModel.xsd, dml-diagramStyleDefinition.xsd, dml-diagramLayoutVariables.xsd, dml-diagramElementPropertySet.xsd, dml-diagramColorTransform.xsd, and dml-diagramDefinition.xsd.

The DrawingML diagram file format is broken down into the following subjects:

- Data Model
- Colors
- Quick Styles

- Layout

The best way to understand the above subjects will be to cover them in the ordering above. The seven schemas can be grouped into the subjects as seen in table 1 below.

Data	Colors	Quick Styles	Layout
dml-diagramDataModel.xsd	dml-diagramColorTransform.xsd	dml-diagramStyleDefinition.xsd	dml-diagramTypes.xsd
dml-diagramElementPropertySet.xsd			dml-diagramDefinition.xsd
			dml-diagramLayoutVariables.xsd
			dml-diagramElementPropertySet.xsd

Table 1: DrawingML schemas grouped by subject.

5.15.2 Element Property Set

The schema dml-diagramElementPropertySet.xsd defines a complex type, CT_ElemPropSet, which is a catch-all for holding element properties and customizations, and is used throughout certain complex types in DrawingML. This type contains many properties, and these are explained in subsequent subclauses. The definition of CT_ElemPropSet is as follows:

```
<xsd:complexType name="CT_ElemPropSet">
  <xsd:sequence>
    <xsd:element name="presLayoutVars"
      type="CT_LayoutVariablePropertySet" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="style" type="a:CT_ShapeStyle"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="presAssocID" type="ST_ModelId" use="optional" />
  <xsd:attribute name="presName" type="xsd:string" use="optional" />
  <xsd:attribute name="presStyleLbl" type="xsd:string" use="optional" />
  <xsd:attribute name="presStyleIdx" type="xsd:int" use="optional" />
  <xsd:attribute name="presStyleCnt" type="xsd:int" use="optional" />
```

```
      <xsd:attribute name="loTypeId" type="xsd:string" use="optional" />
      <xsd:attribute name="loCatId" type="xsd:string" use="optional" />
      <xsd:attribute name="qsTypeId" type="xsd:string" use="optional" />
      <xsd:attribute name="qsCatId" type="xsd:string" use="optional" />
      <xsd:attribute name="csTypeId" type="xsd:string" use="optional" />
      <xsd:attribute name="csCatId" type="xsd:string" use="optional" />
      <xsd:attribute name="coherent3DOff" type="xsd:boolean" use="optional" />
      <xsd:attribute name="phldrT" type="xsd:string" use="optional" />
      <xsd:attribute name="phldr" type="xsd:boolean" use="optional" />
      <xsd:attribute name="custAng" type="xsd:int" use="optional" />
      <xsd:attribute name="custFlipVert" type="xsd:boolean" use="optional" />
      <xsd:attribute name="custFlipHor" type="xsd:boolean" use="optional" />
      <xsd:attribute name="custSzX" type="xsd:int" use="optional" />
      <xsd:attribute name="custSzY" type="xsd:int" use="optional" />
      <xsd:attribute name="custScaleX" type="xsd:int" use="optional" />
      <xsd:attribute name="custScaleY" type="xsd:int" use="optional" />
      <xsd:attribute name="custT" type="xsd:boolean" use="optional" />
      <xsd:attribute name="custLinFactX" type="xsd:int" use="optional" />
      <xsd:attribute name="custLinFactY" type="xsd:int" use="optional" />
      <xsd:attribute name="custLinFactNeighborX" type="xsd:int" use="optional" />
      <xsd:attribute name="custLinFactNeighborY" type="xsd:int" use="optional" />
      <xsd:attribute name="custRadScaleRad" type="xsd:int" use="optional" />
      <xsd:attribute name="custRadScaleInc" type="xsd:int" use="optional" />
    </xsd:complexType>
```

5.15.2.1 Presentation Element Properties

The following attributes deal with presentation elements:

- presLayoutVars – The layout variable property set.
- style – The link to the permutation of the style matrix.
- presAssocID – The semantic element associated with this presentation element. This ID is used together with the presName to create a unique key for presentation element indexing.
- presName – The layout node name of this presentation element. This name is used together with presAssocID to create a unique key for presentation element indexing.
- presStyleLbl – The layout node style label of this presentation element..
- presStyleIdx – The layout node style index of this presentation element..
- presStyleCnt – The layout node style count of this presentation element.

5.15.2.2 Document Element Properties

The following attributes deal with the document element:

- loTypeID – The ID of the current diagram type.
- loCatId – The ID of the current diagram category.

- qsTypeID – The ID of the current style type.
- qaCatID – The ID of the current style category.
- csTypeID – The ID of the current color transform.
- csCatID – The ID of the current color transform category.
- coherent3Doff – Enables or disables coherent 3D behavior for styles that have such behavior defined.

5.15.2.3 Semantic Element Properties

The following attributes relate to the semantic element properties:

- phldrT – The text used for display in the element if the placeholder flag is set to `true`. If this field is not set, then the default placeholder text will be used.
- phldr – Indicates that the element is a placeholder or sample item.

5.15.2.4 Customization Properties

The following are customization properties or tweaks:

- custAng – The amount rotation is customized by, in 60,000th of a degree.
- custFlipVert – Vertical flip.
- custFlipHor – Horizontal flip.
- custSzX – Fixed width override for a shape, in emus.
- custSzY – Fixed height override for a shape, in emus.
- custScaleX – Amount that the width is scaled by, in 1,000th of a percent.
- custScaleY – Amount that the height is scaled by, in 1,000th of a percent.
- custT – If text has been customized then layout will no longer change it.
- custLinFactX – A percentage of the shape width that is used for offsetting the shape, in 1,000th of a percent.
- custLinFactY – A percentage of the shape height that is used for offsetting the shape, in 1,000th of a percent.
- custLinFactNeighborX – A percentage of the neighbor's height used for offsetting the shape, in 1,000th of a percent.
- custLinFactNeighborY – A percentage of the neighbor's height used for offsetting the shape, in 1,000th of a percent.
- custRadScaleRad – Defines how much the radius has been scaled by, in 1,000th of a percent.
- custRadScaleInc – Defines how much the include angle has been scaled by, in 1,000th of a percent.

5.15.3 Data Model

The schema dml-diagramDataModel.xsd defines the data model in a diagram. The purpose of the data model is twofold. The first use of the data model is to hold the information contained in a diagram. For example, in figure 1 below, the purpose of the data model would be to hold the information, "one", "two" and "three" for the diagram.

Figure 11: Example diagram with data.

The second use of the data model is to define an initial state of the diagram. This initial state consists of what can be thought of as placeholder data, which an application uses to display a diagram initially before any data has been entered. Figure 2 shows an example of what a diagram might look like in an initial state containing three empty nodes. In this example, the placeholder data consists of three nodes and two connections, which will be explained shortly.

Figure 12: An empty diagram in its initial state.

5.15.3.1 Structural Elements

5.15.3.1.1 Element Type

There is a single simple type, ST_PtType, used to define a type of element; this is defined later. Element types hold the data associated with a diagram and are defined in relation to one-another through relationship types. Seven different types of elements are available to the user:

- doc – A document element. The document element is the root element within a diagram and can be thought of as the canvas which the diagram is drawn on.
- node – A model element. This is the basic element type which is used and can be used to hold text for example.
- asst – This is used in hierarchy diagrams and represents an assistant element.
- pres – A presentation element. This element defines the visual aspects associated with a node, or rather the presentation aspects of an element.
- parTrans – A parent transition element. This element holds the data for a parent-child relationship between two elements of type node.

- sibTrans – A sibling transition element. This element holds the data for the relationship defined between two elements of type node whom are peers of one another.
- unknown – An element type that is used to maintain backward compatibility.

5.15.3.1.2 Relationship Type

There are defined relationships or connections between two model elements. Four types of relationships are defined in the simple type ST_CxnType:

- parOf – Parent-child relationship.
- presOf – Presentation relationship.
- presParOf – Presentation parent of relationship.
- unknownRelationship – An unknown relationship type.

5.15.3.1.3 Element

An element is a single item, such as a node or transition in the data model. Within the realm of DrawingML, the complex type CT_Pt holds information describing an element within a diagram. Within this description lies both the data held within the element, and any formatting on that element. A CT_Pt is defined as follows:

```
<xsd:complexType name="CT_Pt">
  <xsd:sequence>
    <xsd:element name="prSet" type="CT_ElemPropSet" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="spPr" type="a:CT_ShapeProperties"
      minOccurs="0" maxOccurs="1 />
    <xsd:element name="style" type="a:CT_ShapeStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="t" type="a:CT_TextBody" minOccurs="0"
      maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="modelId" type="ST_ModelId" use="required" />
  <xsd:attribute name="type" type="ST_PtType" use="optional"
    default="node" />
  <xsd:attribute name="cxnId" type="ST_ModelId" use="optional"
    default="0" />
</xsd:complexType>
```

The attribute modelId holds a unique id for a particular element. This unique id can be referenced elsewhere, for example, from within a connection list. This attribute is required for every point defined in the data model.

The last two attributes of the CT_Pt are optional. The first defines the type of point with the default being a node. The second defines a connection id. This connection id is only used if the point type is of type parTrans, or sibTrans. The connection id refers to a relationship that is defined elsewhere in the data model.

5.15.3.1.4 Relationship

A relationship is a connection between any two model elements. An example of where a relationship would be used can be seen in figures 1 and 2. In each of those examples, the arrows between the nodes have relationships defined. A relationship is defined as follows:

```
<xsd:complexType name="CT_Cxn>
  <xsd:attribute name="modelId" type="ST_ModelId" use="required" />
  <xsd:attribute name="type" type="ST_CxnType" use="optional"
    default="parOf" />
  <xsd:attribute name="srcId" type="ST_ModelId" use="required" />
  <xsd:attribute name="destId" type="ST_ModelId" use="required" />
  <xsd:attribute name="srcOrd" type="xsd:unsignedInt" use="required" />
  <xsd:attribute name="destOrd" type="xsd:unsignedInt" use="required" />
  <xsd:attribute name="parTransId" type="ST_ModelId" use="optional"
    default="0" />
  <xsd:attribute name="sibTransId" type="ST_ModelId" use="optional"
    default="0" />
  <xsd:attribute name="presId" type="xsd:string" use="optional"
    default="" />
</xsd:complexType>
```

The relationship, as with the element, has a unique id associated with it referred to as the modelID. The srcId and destId attributes refer to ids of the source element and destination element, respectively, that this relationship is defined between.

The srcOrd and destOrd refer to the ordinality of siblings for a given connection. For example, if a node had three siblings, A, B, and C, then the srcOrd would define if they were to show up as A, B, C, or perhaps B, C, and then A.

The presId attribute contains the presentation that is associated with this particular relationship.

5.15.3.1.5 Element List

The complex type CT_PtList is simply a sequence of elements. Its definition is as follows:

```
<xsd:complexType name="CT_PtList">
  <xsd:sequence>
    <xsd:element name="pt" type="CT_Pt" minOccurs="0" maxOccurs="unbounded"/>
  </xsd:sequence>
</xsd:complexType>
```

5.15.3.1.6 Relationship List

This complex type, CT_CxnList, is simply a sequence of connections. Its definition is as follows:

```
<xsd:complexType name="CT_CxnList" oxsd:cname="Relationships">
  <xsd:sequence>
    <xsd:element name="cxn" type="CT_Cxn" minOccurs="0"
      maxOccurs="unbounded" />
  </xsd:sequence>
</xsd:complexType>
```

5.15.3.1.7 Data Model

The complex type CT_DataModel defines the data model and contains a sequence of elements. It is defined as follows:

```
<xsd:complexType name="CT_DataModel">
  <xsd:sequence oxsd:emitArgs="flattenSequence">
    <xsd:element name="ptLst" type="CT_PtList" />
      <xsd:element name="cxnLst" type="CT_CxnList" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="bg" type="a:CT_BackgroundFormatting"
        minOccurs="0" />
      <xsd:element name="whole" type="a:CT_WholeE2oFormatting"
        minOccurs="0" />
    </xsd:sequence>
</xsd:complexType>
```

The data model contains a list of elements, a list of connections, and formatting properties for the background object and the diagram container. This complex type is responsible for holding all data-bound information of the diagram being created.

5.15.4 Color Transforms

Color transforms define how colors are applied to diagrams. Color transforms define how color is used in the diagram as a whole, and they mandate things such as which theme color or colors will be used, if there is a tint or shade applied to a certain color or part of the diagram, or if color is even used at all. Some examples of what color transforms can do to a simple diagram can be seen in figure 3.

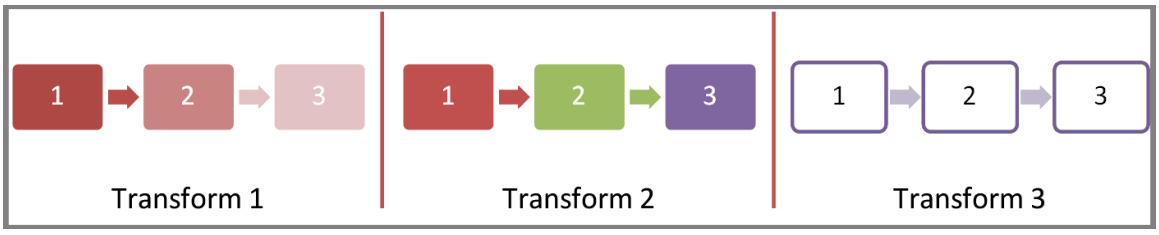


Figure 13: Different examples of a color transform applied to a diagram

5.15.4.1 Structural Elements

The structural elements which come together to create a color transform, or rather, the complex type CT_ColorTransform, are as follows:

- CT_CTName
- CT_CTDescription
- CT_CTCategory
- CT_CTCategories
- ST_ClrAppMethod
- ST_HueDir
- CT_Colors
- CT_CTStyleLabel
- CT_CTVersion
- CT_ColorTransformHeader
- CT_ColorTransformHeaderLst

The complex types CT_CTName (name), CT_CTDescription (description), CT_CTCategory (category), and CT_CTCategories (list of categories) work together to name, describe and categorize the particular color transform. These types are mirrored elsewhere throughout DrawingML in the different subjects in order to perform the same tasks of naming, describing, and categorizing.

The name consists simply of two strings, one of a name for the color transform, which is required, and an optional language tag. The language allows someone to specify a language for a given title. It is possible to specify multiple titles that are language dependant. The description also has the optional language attribute as in the name, along with a second required string attribute which holds the actual description. The usage of this is exactly the same as within CT_CTName. CT_CTName and CT_CTDescription are defined in the following way:

```
<xsd:complexType name="CT_CTName">
  <xsd:attribute name="lang type="xsd:string" use="optional" />
  <xsd:attribute name="val" type="xsd:string" use="required" />
</xsd:complexType>
<xsd:complexType name="CT_CTDescription">
  <xsd:attribute name="lang" type="xsd:string" use="optional" />
  <xsd:attribute name="val" type="xsd:string" use="required" />
</xsd:complexType>
```

The category and categories complex types , CT_CTCategory and CT_CTCategories, respectively, define how the color transform is categorized within the user interface of the application. The category contains a name, or type, along with a priority that defines the ordering of the color transform. The lower the priority, the earlier in the category it will display. If there is a tie, the unique id associated with the color transform will decide the order alphabetically. CT_CTCategories is simply a list of CT_CTCategory. The two complex types are defined as follows:

```
<xsd:complexType name="CT_CTCategory">
  <xsd:attribute name="type" type="xsd:anyURI" use="required" />
  <xsd:attribute name="pri" type="xsd:unsignedInt" use="required"/>
</xsd:complexType>
<xsd:complexType name="T_CTCategories">
  <xsd:sequence minOccurs="0" maxOccurs="unbounded">
    <xsd:element name="cat" type="CT_CTCategory" minOccurs="0"
      maxOccurs="unbounded" />
  </xsd:sequence>
</xsd:complexType>
```

5.15.4.1.1 Color Application Method

The simple type ST_ClrAppMethod lists the different options for color to be applied to a diagram. There are three options available to the user: span, cycle, and repeat. Given a list of colors, which go from color A to color B, the differences in these three options can be defined. These options are shown below in Figure 4.

The span option will, from the start of the diagram to the end of the diagram, interpolate between the colors A through B for every node along the way.

The cycle option will interpolate from A to B then back to A from the start of the diagram to the end of the diagram.

The repeat option applies colors A through B one at a time for each point in the diagram, then repeats A through B as needed.

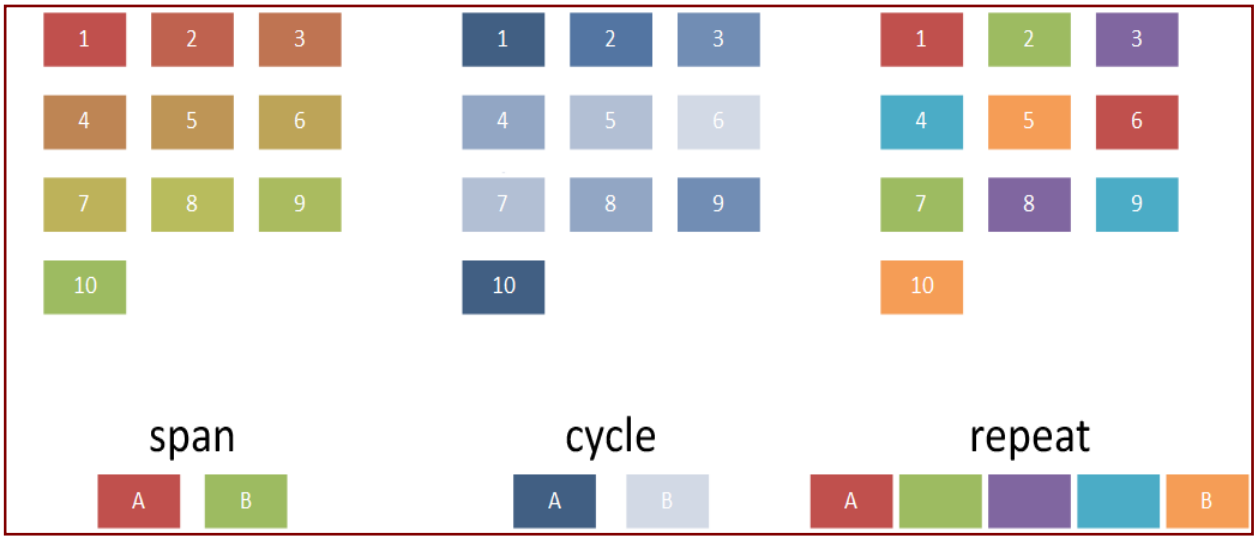

Figure 14: Examples of the three different ways a color transform is applied to a diagram.

5.15.4.1.2 Hue Direction

The simple type ST_HueDir defines the direction of a hue color shift around a color wheel. A user can either define the shift to occur in the clockwise (cw) direction, or in the counterclockwise (ccw) direction. For

example, in Figure 4, the span colors are red and green. The behavior shown in figure 4 is a shift in the cw direction. If the hue shift had been defined in the ccw direction, the colors interpolated between colors A and B would have been in the hues purple and blue. Another example of a hue direction shift in the clockwise can be seen in Figure 5 below along with the color shift from red to yellow and then from yellow to blue along the primary colors. Counterclockwise shifts would occur in the direction of yellow to red and blue to yellow in the examples below.

Figure 15: Example hue shifts in the clockwise direction around a color wheel applied to two diagrams. The three primary colors, red, yellow, and blue are used to represent the three major sections of a color wheel which ranges between red to yellow to blue to red.

5.15.4.1.3 Colors

The complex type CT_Colors holds the actual color values that are to be applied to a given diagram and how those colors are to be applied. It contains the color application method and hue shift direction, and is defined as follows:

```
<xsd:complexType name="CT_Colors>
  <xsd:sequence>
    <xsd:group ref="a:EG_ColorChoice" minOccurs="0" maxOccurs="unbounded" />
  </xsd:sequence>
  <xsd:attribute name="meth" type="ST_ClrAppMethod" use="optional"
    default="span" />
  <xsd:attribute name="hueDir" type="ST_HueDir" use="optional"
    default="cw" />
</xsd:complexType>
```

The sequence of colors is defined via the sequence of EG_ColorChoices.

5.15.4.1.4 Style Label

The complex type CT_CTStyleLabel packages together colors for the different pieces of a diagram. There are six different aspects to a diagram that can be colored independently of one another. Each of the six parts is of type CT_Colors. They are:

- Fill Colors – The colors that actually fill the shapes in the diagram
- Line Colors – The colors of the lines on the shapes in the diagram.
- Effect Colors – The colors of the effects applied to the shapes within the diagram (eg. Glow).
- Text Line Colors – The colors of the lines on the text within the diagram.
- Text Fill Colors – The color of the text within the diagram.
- Text Effect Colors – The colors of the effects applied to the text within the diagram.

The final piece of a style label is simply its name, which is a string. CT_CTStyleLabel is defined as follows:

```
<xsd:complexType name="CT_CTStyleLabel">
  <xsd:sequence>
    <xsd:element name="fillClrLst" type="CT_Colors"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="linClrLst" type="CT_Colors"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="effectClrLst" type="CT_Colors"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="txLinClrLst" type="CT_Colors"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="txFillClrLst" type="CT_Colors"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="txEffectClrLst" type="CT_Colors"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="name" type="xsd:string" use="required" />
</xsd:complexType>
```

5.15.4.1.5 Version

The simple type ST_CTVersion defines the minimum version of an application that the color transform will work with. The version corresponds to build numbers in the major.minor.build.revision format and is defined as follows:

```
[0-9]?[0-9])?(\.[0-9]?[0-9])?(\.[0-9]{4})?(\.[0-9]{4}
```

5.15.4.1.6 Color Transform

The complex type CT_ColorTransform brings together all of the pieces into one cohesive structure. This is the actual definition of a color transform, which can be applied to any diagram; it is defined as follows:

```
<xsd:complexType name="CT_ColorTransform">
  <xsd:sequence>
    <xsd:element name="title" type="CT_CTName" minOccurs="0"
      maxOccurs="unbounded" />
    <xsd:element name="desc" type="CT_CTDescription"
      minOccurs="0" maxOccurs="unbounded" />
    <xsd:element name="catLst" type="CT_CTCategories"
      minOccurs="0" />
    <xsd:element name="styleLbl type="CT_CTStyleLabel"
      minOccurs="0" maxOccurs="unbounded" odoc />
  </xsd:sequence>
  <xsd:attribute name="uniqueId" type="xsd:anyURI" use="optional"/>
  <xsd:attribute name="minVer" type="ST_CTVersion" use="optional"
    default="12.0" />
</xsd:complexType>
```

A color transform contains a title, description, category list, and style label in a sequence along with a unique id and a minimum version.

5.15.4.2 Color Transform Header

Two complex types, CT_ColorTransformHeader and CT_ColortransformHeaderLst, help alleviate potential performance concerns with initially loading in a large number of color transforms. The header information contains the minimum information required to load a color transform into the application. Because of this, color transforms themselves can be loaded only when needed, and other initialization work can progress quickly without loading unneeded information.

CT_ColorTransformHeader contains information about the title of the color transform, the description, how it is categorized, the unique id, minimum version, and resId. It is defined in the following way:

```
<xsd:complexType name="CT_ColorTransformHeader">
  <xsd:sequence>
    <xsd:element name="title" type="CT_CTName" minOccurs="1"
      maxOccurs="unbounded" />
    <xsd:element name="desc" type="CT_CTDescription"
      minOccurs="1" maxOccurs="unbounded" />
    <xsd:element name="catLst" type="T_CTCategories"
      minOccurs="0" o:cname="categories" />
  </xsd:sequence>
  <xsd:attribute name="uniqueId" type="xsd:anyURI" use="required"/>
  <xsd:attribute name="minVer" type="ST_CTVersion" use="optional"
    default="12.0" />
  <xsd:attribute name="resId" type="xsd:int" use="optional"
  default="0" />
</xsd:complexType>
```

The complex type CT_ColorTransformHeaderLst simply contains a list of color transform headers. It is defined as follows:

```
<xsd:complexType name="CT_ColorTransformHeaderLst">
  <xsd:sequence>
    <xsd:element name="colorsDefHdr" type="CT_ColorTransformHeader"
      minOccurs="0" maxOccurs="unbounded" />
  </xsd:sequence>
</xsd:complexType>
```

5.15.5 Style Definition

A style definition is similar to a color transform. A style definition defines items such as the font used, the thickness of a contour line, 3-D properties on the diagram, among other things. Style definitions work in combination with color transforms to give an overall look and feel for the diagram. Some examples of style definitions in use are in figure 5.

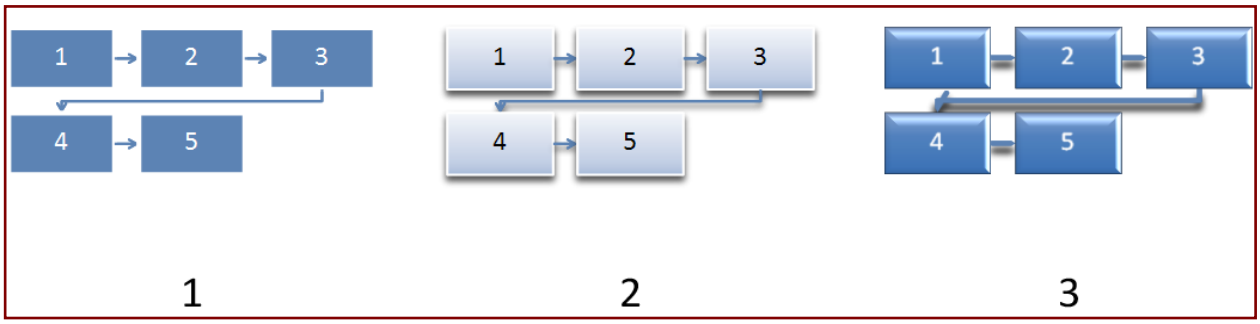

Figure 16: Examples of using three different style definitions on a diagram.

5.15.5.1 Structural Elements

The structural elements which come together to create a style definition are as follows:

- CT_SDName
- CT_SDDescription
- CT_SDCategory
- CT_SDCategories
- CT_TextProps
- CT_StyleLabel
- ST_SDVersion
- CT_StyleDefinition
- CT_StyleDefinitionHeader
- CT_StyleDefinitionHeaderLst

CT_SDName, CT_SDDescription, CT_SDCategory, CT_SDCategories, and ST_SDVersion are all defined exactly as they are within color transforms. These types were recreated within the style definition area to allow slight differentiations to be made, although, at this time they are defined exactly the same.

The text properties, style label, and then the style definition combine together to create a style definition, which is applied to a diagram.

5.15.5.1.1 Text Properties

The complex type CT_TextProps holds any 3-D associated properties of the text that is to be held in the diagram. A CT_TextProps is defined as follows:

```
<xsd:complexType name="CT_TextProps">
  <xsd:sequence>
    <xsd:group ref="a:EG_Text3D" minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
</xsd:complexType>
```

All that is contained within the text properties is an EG_Text3D complex type. The usage of the text properties complex type allows 3-D text properties to be defined for a diagram style.

5.15.5.1.2 Style Label

The style label contains information pertaining to the styleable elements within a diagram. These elements include the shape properties and text properties along with any references to the style matrix or document theme. The shape properties are defined in two different ways: the scene3d element that pertains to the scene on a whole (and includes lighting effects, rotations, and the like), and any 3-D and material settings are held in the sp3d element. CT_StyleLabel is defined as follows:

```
<xsd:complexType name="CT_StyleLabel">
  <xsd:sequence>
    <xsd:element name="scene3d" type="a:CT_Scene3D"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="sp3d" type="a:CT_Shape3D" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="txPr" type="CT_TextProps" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="style" type="a:CT_ShapeStyle"
      minOccurs="0" maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="name" type="xsd:string" use="required" />
</xsd:complexType>
```

As with many other complex types, the style label has an attribute reserved for a name. This is simply a string that names the particular style label. This style label can then be referenced from within a diagram definition, as we shall see below.

Note that the scene3d element contained within a style label acts on the level of an individual shape, rather than the diagram as a whole. A second scene3d element is defined within the style definition; that acts on the diagram level and allows for scene coherent 3-D to be applied to the diagram. A style definition contains a style label.

5.15.5.1.3 Style Definition

The style definition complex type, CT_StyleDefinition, is the root element used to define a style definition. As with the root element of a color transform, within the style definition there exists a title, description, category, unique id, and minimum version number. These elements serve the same purpose as they do within the color transform.

The interesting aspects of a style definition complex type are that it holds a style label, another style index (which is contained within the style label as well), and another scene3d (which is also contained within the style label as has been previously mentioned). The scene3d element applies to the diagram on a whole and allows for scene coherent 3-D to be applied to the diagram. The duplication of the style index is two-fold. If a style index is not defined within the style label, then the default style index, or rather, the index defined in this complex typem is used. Since a diagram definition can reference a style label, and not a style definition, the style index is also required within the style label. A CT_StyleDefniition is defined as follows:

```
<xsd:complexType name="CT_StyleDefinition">
  <xsd:sequence>
    <xsd:element name="title" type="CT_SDName" minOccurs="0"
      maxOccurs="unbounded" />
    <xsd:element name="desc" type="CT_SDDescription"
  minOccurs="0" maxOccurs="unbounded" />
    <xsd:element name="catLst" type="CT_SDCategories"
      minOccurs="0" />
    <xsd:element name="scene3d" type="a:CT_Scene3D"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="style" type="a:CT_ShapeStyle"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="styleLbl" type="CT_StyleLabel"
      minOccurs="1" maxOccurs="unbounded" />
  </xsd:sequence>
  <xsd:attribute name="uniqueId" type="xsd:anyURI" use="optional"/>
  <xsd:attribute name="minVer" type="ST_SDVersion" use="optional" `
    default="12.0" />
</xsd:complexType>
```

5.15.5.1.4 Style Definition Header

The complex types CT_StyleDefinitionHeader and CT_StyleDefinitionHeaderLst perform the same function as the two complex header types in color transforms. They are used to pre-load required information so the actual loading of the style definition can happen only when needed.

5.15.6 Layout

The single largest aspect of DrawingML is Layout. Ultimately, layout is responsible for defining all aspects of the diagram outside of color and style. It defines how the diagram looks, how it behaves, and how the data is to be mapped. Figure 6 shows different examples of how layout works to create a diagram holding the data '1', '2', and '3'.

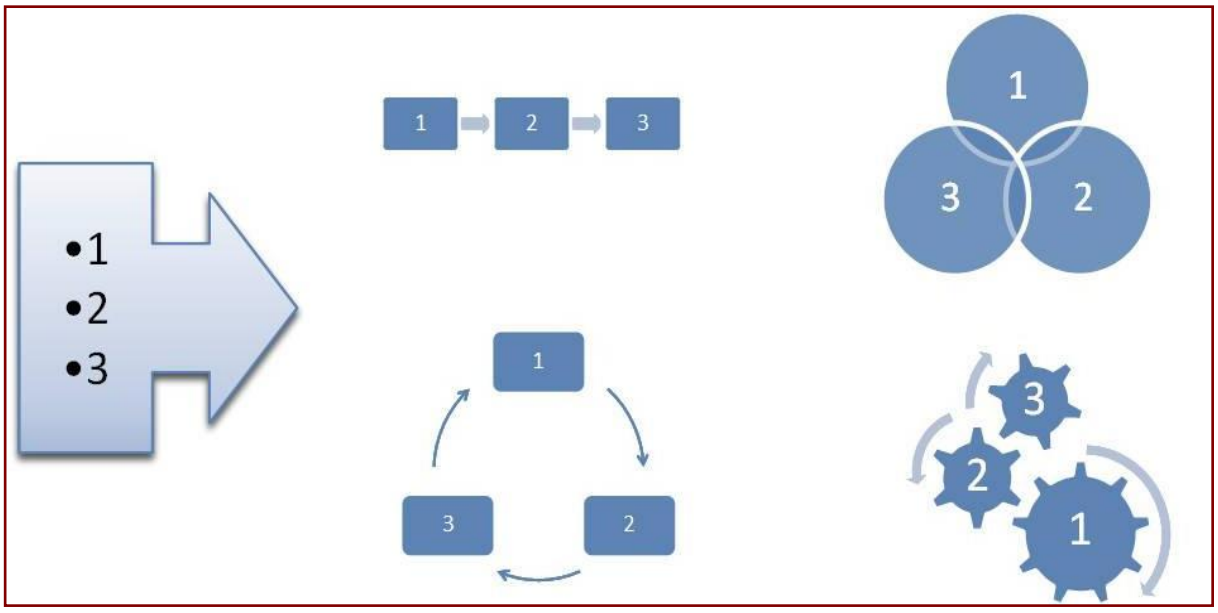

Figure 17: Different layouts mapping the data 1, 2, and 3 to four different diagrams

There are two aspects to layout: defining the numerous complex types utilized by diagram definitions, and the diagram definitions themselves. Diagram definitions are a fundamental part of layout, and utilize everything in order to define new diagrams.

5.15.6.1 Basic Layout Types

There are a very large number of simple types defined in this subject. These simple types are all associated with properties of a diagram that can be modified to create a desired behavior. These simple types, along with an explanation of what each does, follow.

5.15.6.1.1 Algorithm Type

ST_AlgorithmType is responsible for which algorithm will be used to layout the diagram. The algorithm layout chosen determines if the diagram behaves as if it were a simple list, a circular cycle, or some other type of diagram. The algorithms available are:

- unknown – Unknown algorithm type. This type is used for extensibility reasons. Use of this algorithm type can used by future versions/implementations which define new algorithm types other than the above mentioned algorithm types. By using this type, the current implementations know that they will not be able to correctly render the diagram if they have only implemented the above mentioned algorithms for layout.

- composite – The composite algorithm specifies the size and position for all child layout nodes. You can use it to create graphics with a predetermined layout or in combination with other algorithms to create more complex shapes.
- conn – the connector algorithm lays out and routes connecting lines, arrows, and shapes between layout nodes
- cycle – the cycle algorithm lays out child layout nodes around a circle or portion of a circle using equal angle spacing
- hierChild – the hierarchy child algorithm works with the hierRoot algorithm to create hierarchical tree layouts. This algorithm aligns and positions its child layout nodes in a linear path under the hierRoot layout node.
- hierRoot – the hierarchy root algorithm works with the hierChild algorithm to create hierarchical tree layouts. The hierRoot algorithm aligns and positions the hierRoot layout node in relation to the hierChild layout nodes.
- pyra – the pyramid algorithm lays out child layout nodes along a vertical path and works with the trapezoid shape to create a pyramid
- lin – the linear algorithm lays out child layout nodes along a linear path
- sp – the space algorithm is used to specify a minimum space between other layout nodes or as an indication to do nothing with the layout node's size and position
- tx – manges layout of text within a shape
- snake – the snake algorithm lays out child layout nodes along a linear path in two dimensions, allowing the linear flow to continue across multiple rows or columns

5.15.6.1.2 Axis Type

The simple type ST_AxisType defines how layout maps data to the diagram for a given point in the diagram. The different ways this can be mapped is as follows:

- self – the layout maps to the current data point
- ch – the layout node can map to the children of the current data point, but not to descendants lower in the hierarchy
- des – the layout node can map to a descendant of the current data point
- desOrSelf – the layout node can map the current data point, or to a descendant of the current data point
- par – the layout node maps to the parent data point
- ancst – the layout node can map to the ancestors of the current data point (parents, grandparents, great grandparents, etc)
- ancstOrSelf – the layout node can map an ancestor data point or the current data point
- followSib – the layout node can map to a following sibling peer to the current data point
- precedSib – the layout node can map to a preceding sibling peer to the current data point.
- root – the layout node can map to the root
- none – the layout node doesn't map to any data point

5.15.6.1.3 Boolean Operators

Boolean type operators, defined by ST_BoolOperator, are for layout.

- none – no operator defined
- equ – 'equal to' operator, returns true if the two compared values are equal, false otherwise
- gte – 'greater than or equal to' operator
- lte – 'less than or equal to' operator

5.15.6.1.4 Child Order Type

The simple type ST_ChildOrderType specifices the child order type for a layout node.

- b – bottom
- t – top

5.15.6.1.5 Constraint Types

The simple type ST_ConstraintTypes defines the constraints that can be used as limits or modifications to the diagram or the nodes held within the diagram. These constraints manage the behavior of many properties that can be defined within the diagram. The different constraints that can be applied to a diagram are as follows:

- unknown – An unknown constraint. This can be used by implementing applications to define a constraint type outside of the scope of what is defined by this simple type.
- alignOff – specifies the alignment offset
- begMarg – specifies the beginning margin
- bendDist – specifies the distance at which a connector will bend
- begPad – specifies the distance between the edge of the transition node and the connector shape
- b – bottom alignment
- bMarg – the bottom margin
- bOff – specifies the amount of offset relative to the bottom of the node
- ctrX – specifies the center of the node in the X-direction
- ctrXOff – specifies the amount of offset of the center of the node in the X-direction
- ctrY – specifies the center of the node in the Y-direction
- ctrYOff – specifies the amount of offset of the center of the node in the Y-direction
- connDist – specifies the distance between connectors. Intended for use with boolean and reference constraints. Overrides values specified in the layout definition part
- diam – specifies the diameter, and is used within the cycle algorithm type
- endMarg – specifies the end margins
- endPad – specifies the distance between the edge of the transition node and the connector shape
- h – specifies the height
- hArH – specifies the arrowhead height
- hOff – specifies the height offset

- l – specifies the left
- lMarg – specifies the amount of left margin
- lOff – specifies the amount of left offset
- r – specifies right
- rMarg – specifies the amount of right margin
- rOff – specifies the amount of right offset
- primFontSz – specifies the primary font size
- pyraAcctRatio - specifies the fraction of the width of the diagram that is reserved for the fly-outs at their shortest distance
- secFontSiz – specifies the secondary font size
- stemThick – specifies the thickness of the shaft on an arrow
- t – specifies the top
- tMarg – specifies the amount of top margin
- tOff – specifies the amount of top offset
- userA through userZ – User defined information. This set of enumerations allow a user to define specific values which can be referenced at a later time within a diagram definition. For example, if the value 5.1 was important to the layout and definition of a diagram, the user could define userA to be equal to 5.1 and then use the userA constraint within the diagram definition. This would allow a single place to update the value across the entire diagram definition.
- w – specifies the width
- wArH – specifies the width of an arrowhead
- wOff – specifies the amount of width offset

5.15.6.1.6 Constraint Relationships

The simple type ST_ConstraintRelationship defines the application of retrieval data the constraint is applied to. The following relationships are available:

- self – the constraint is applicable to the current point
- ch – the constraint is applicable to a child of the current point
- des – the constraint is applicable to a descendant of the current point

5.15.6.1.7 Element Type

The simple type ST_ElementType defines the type of element, or point which get created and how they are created from the data at hand. The different ways to pull from the data to create points are as follows:

- all – use all of the data points, nodes and transitions
- doc – use the document level, or root data point
- node – use only data nodes input by the user
- norm – in place for extensibility and behaves exactly opposite of the asst element type
- nonNorm – in place for extensibility and behaves exactly opposite of the nonAsst element type
- asst – use assistant data nodes within hierarchy algorithm

- nonAsst – use non-assistant nodes within the hierarchy algorithm
- parTrans – Use only parent transitions between nodes. Parent transitions are similar to sibling transitions, except that they represent parent/child relationships. Parent transitions are most commonly used in hierarchy diagrams, such as organization charts, to draw lines between parent and child nodes.
- pres – specifies that the node is related to the presentation level
- sibTrans – Use only sibling transitions between data nodes. These transitions represent sibling relationships between nodes, and are frequently mapped to arrows between shapes in the drawing. A sibTrans value is sometimes used to create white space between nodes.

5.15.6.1.8 Parameter ID

The simple type ST_ParameterId defines parameters that can be used to modify the behavior or algorithms. The modifications are as follows:

- horzAlign – specifies the horizontal alignment
- vertAlign – specifies the vertical alignment
- chDir – specifies the child direction
- chAlign – specifies the alignment of the children
- secChAlign – specifies a secondary child alignment
- linDir – specifies whether children are arranged from left to right, right to left, top to bottom, or bottom to top
- secLinDir – specifies a secondary linear direction in which children are
- arranged from left to right, right to left, top to bottom, or bottom to top
- stElem – specifies the point type of the layout node to use as the first shape in the cycle
- bendPt – specifies where the bend point is to be located on connectors
- connRout – specifies whether the connector is drawn as a single straight line, orthogonal lines with a single bend, or a curve that uses the diam constraint
- begSty – specifies whether the beginning of the connector has an arrowhead
- endSty – specifies whether the end of the connector has an arrowhead
- dim – specifies the connector dimension, 2-D, 3-D, or custom
- rotPath - if rotPath=`alongPath`, the algorithm rotates all children perpendicular to the line from the cycle's center to the child node; otherwise they are not rotated. The `alongPath` value does not take rotation into account when determining if shapes overlap
- ctrShpMap - `None` specifies to place nodes around a circle. First node (`fNode`) specifies to place the first node in the center and the remaining nodes around the circle
- nodeHorzAlign – specifies the horizontal node alignment
- nodeVertAlign – specifies the vertical node alignment
- fallback – specifies if the fallback occurs in a single dimension (e.g. vertically) or if it occurs in two dimensions
- txDir – specifies where the text of the first node starts
- pyraAcctPos – specifies the placement of the fly-out grandchildren

- pyraAcctTxMar – specifies the placement of one edge of the child text
- txBlDir – Specifies the text block direction, vertical or horizontal
- txAnchorHorz – Specifies the horizontal text anchor position.
- txAnchorVert – Specifies the vertical text anchor position.
- txAnchorHorzCh – Specifies the horizontal text anchor position for child text.
- txAnchorVertCh – Specifies the vertical text anchor position for child text.
- parTxLTRAlign – Specifies the paragraph alignment of parent text when the shape has only parent text. This parameter applies when the text direction is left to right.
- partTxRTLAlign – Specifies the paragraph alignment of parent text when the shape has only parent text. This parameter applies when the text direction is right to left.
- shpTxLTRAlignCh – Specifies the paragraph alignment of all text within the shape when the shape contains both parent and child text. This parameter applies when the text direction is left to right.
- shpTxRTLAlignCh – Specifies the paragraph alignment of all text within the shape when the shape contains both parent and child text. This parameter applies when the text direction is right to left.
- autoTxRot – specifies how text is oriented relative to the shape
- grDir – Specifies the direction of growth for the snake algorithm.
- flowDir – specifies weather nodes are arranged in rows or columns for the snake algorithm.
- contDir – Specifies the direction of subsequent rows or columns in the snake algorithm.
- bkpt – specifies the point at which the diagram starts to snake
- off – specifies whether each row and column is centered or offset from the previous row or column
- hierAlign – specifies the alignment of the hierarchy
- bkPtFixedVal – specifies where the sname should break if bkpt is set to fixed
- stBulletLvl – Specifies the level at which to start using bullets for incoming text.
- stAng – Specifies the angle at which the first shape is placed. Angles are in degrees, measured clockwise from a line pointing straight upward from the center of the cycle.
- spanAng – Specifies the angle the cycle spans. Final shapealign text is placed at stAng+spanAng, unless spanAng=360. In that case, the algorithm places the text so that shapes do not overlap
- ar – Specifies the aspect ratio (width to height) of the composite node to use when determining child constraints. A value of 0 means leave the width and height constraints as is. The algorithm may temporarily shrink one dimension to achieve that ratio
- lnSpPar – specifies the line spacing of the parent
- lnSpAfParP – specifies the line spacing after the parent paragraph
- LnSpCh specifies the line spacing of a child
- lnSpAfChP – specifies the line spacing after the child paragraph
- rtShortDist – Specifies the routing to use the shortest distance for connectors.
- alignTx – specifies if to hold text or not
- pyraLvlNode – If pyramid has a composite child node, specifies the name of the node that is a child of the composite that makes up the pyramid itself. If the node specifies a trapezoid shape, it modifies the adjustment handles to construct a pyramid.

- pyraAcctBkgdNode – If pyramid has a composite child node, specifies the child node that should hold the child text.
- pyraAcctTxNode – If pyramid has a composite child node, specifies the name of the node that is a child of the composite that makes up the child flyout shape.
- srcNode – Specifies the name of the layout node from which to start the connection.
- dstNode – Specifies the name of the layout node from which to end the connection from.
- begPts – Specifies the point type for the beginning of a connector.
- endPts – Specifies the point type for the end of a connector.
- unknown – An unkown parameter id. This can be used by implementing applications to define a parameter id outside of the scope of what is defined by this simple type.

5.15.6.1.9 Function Type

The simple type ST_FunctionType defines different types of conditional expressions that can be utilized. The different types of expressions are:

- cnt – Specifies the count of items.
- pos - Retrieves the position of the node in the specified set of nodes.
- revPos - Reverse position function.
- posEven - Returns 1 if the specified node is at an even numbered position in the data model.
- posOdd - Returns 1 if the specified node is in an odd position in the data model.
- var - Used to reference a variable.
- depth - Specifies the depth of items.
- maxDepth - Defines the maximum depth of items.

5.15.6.1.10 Function Operator

The simple type ST_FunctionOperator defines the different condition expression operators that can be used. The different operators are as follows:

- equ – equal
- neq – not equal
- gt – greater than
- lt – less than
- gte – greater than or equal to
- lte – less than or equal to

5.15.6.1.11 Horizontal Alignment

The simple type, ST_HorizontalAlignment, specifies the different options available for alignment horizontally. The options are:

- l – left
- ctr – center
- r – right

- none – none

5.15.6.1.12 Vertical Alignment

The simple type, ST_VerticalAlignment, specifies the different options available for alignment vertically. The options are:

- t – top
- mid – middle
- b – bottom
- none – none
- Child Direction

The simple type ST_ChildDirection is used to specify the direction the children are laid out. The different options are:

- horz – horizontally
- vert – vertically

5.15.6.1.13 Child Alignment

The simple type ST_ChildAlignment defines the alignment parameter types for children. The different types are:

- t – top
- b – bottom
- l – left
- r – right

5.15.6.1.14 Secondary Child Alignment

The simple type ST_SecondaryChildAlignment defines secondary alignment parameter types for children. The simple type ST_ChildAlignment is mirrored here with the addition of the none type.

5.15.6.1.15 Linear Direction

The simple type ST_LinearDirection defines the linear direction parameter types. The types are as follows:

- fromL – from left
- fromR – from right
- fromT – from top
- fromB – from bottom

5.15.6.1.16 Secondary Linear Direction

The simple type ST_SecondaryLinearDirection defines a secondary linear direction parameter. This simple type mirrors exactly the simple type ST_LinearDirection with the addition of the none type.

5.15.6.1.17 Starting Element

The simple type ST_StartingElement specifies the first node point type for a cycle diagram. The different starting elements are:

- node – node
- trans – transition

5.15.6.1.18 Rotation Path

The simple type ST_RotationPath specifies the way in which the algorithm rotates children. The different rotation types are:

- none – no rotation is performed
- alongPath – the children are rotated perpendicular to the line from the cycle's center to the child node

5.15.6.1.19 Center Shape Mapping

The simple type ST_CenterShapeMapping specifies how the first node of a cycle diagram is laid out within the diagram. The different places to put the first node are:

- none – the node is laid out around the circle
- fNode – the node is placed in the center of the circle and the remaining nodes along the outside of the circle

5.15.6.1.20 Bend Point

The simple type ST_BendPoint specifies where the bend point is to be located along elbow connectors. The different options are:

- beg – beginning
- def – default
- end – end

5.15.6.1.21 Connector Routing

The simple type ST_ConnectorRouting defines how the routing of a connector happens within the diagram. The different routing options are:

- stra – straight
- bend – an elbow connection
- curve – a curved connection
- longCurve – a curved connection with a larger radius than simple curve

5.15.6.1.22 Arrowhead Style

The simple type ST_ArrowheadStyle defines the style of the arrowhead used on a connector. The different options are:

- auto – automatic
- arr – an arrowhead is used
- noArr – no arrowhead is used

5.15.6.1.23 Connector Dimension

The simple type ST_ConnectorDimension defines the dimension of a connector used in a diagram. The different dimension types are:

- 1D – a single dimension connector, for example, a line
- 2D – a two dimensional connector, for example, an arrow
- cust – custom

5.15.6.1.24 Connector Point

The simple type ST_ConnectorPoint defines the point at which the connector starts and ends. The different beginning and ending types are:

- auto – automatic
- bCtr – bottom center
- ctr – center
- midL – middle left
- midR – middle right
- tCtr – top center
- bL – bottom left
- bR – bottom right
- tL – top left
- tR – top right
- radial – radial

5.15.6.1.25 Node Horizontal Alignment

The simple type ST_NodeHorizontalAlignment defines the alignment of a node in the horizontal direction. The different alignments are:

- l – left
- ctr – center
- r – right

5.15.6.1.26 Node Vertical Alignment

The simple type ST_NodeVerticalAlignment defines the alignment of a node in the vertical direction. The different alignments are:

- t – top
- mid – mid

- b – bottom

5.15.6.1.27 Fallback Dimension

The simple type ST_FallbackDimension defines how many dimensions fallback will resize the diagram in. The different options for fallback dimension are:

- 1D – fallback occurs in a single dimension (X or Y)
- 2D – fallback occurs in two dimensions (X and Y)

5.15.6.1.28 Text Direction

The simple type ST_TextDirection specifies where the text on the first node starts. The different text directions are:

- fromT – from top
- fromB – from bottom

5.15.6.1.29 Pyramid Accent Position

The simple type ST_PyramidAccentPosition defines where the position of the fly-out grandchildren. The possible positions are:

- bef – before
- after – after

5.15.6.1.30 Pyramid Text Margin

The simple type ST_PyramidAccentTextMargin specifies the alignment of the text in the fly-out grandchildren. The different alignments are:

- step – the text is against the edge of the pyramid
- stack – the text aligns

5.15.6.1.31 Text Block Direction

The simple type ST_TextBlockDirection defines the text block direction. The different direction the text can have are:

- vert – vertical
- horz – horizontal

5.15.6.1.32 Text Anchor Horizontal

The simple type ST_AnchorHorizontal is responsible for anchoring text horizontally. The available options are:

- none – no anchor set
- ctr – the text is anchored the center

5.15.6.1.33 Text Anchor Vertical

The simple type ST_AnchorVertical is responsible for anchoring the text vertically. The available options are:

- t – top anchor
- mid – middle anchor
- b – bottom anchor

5.15.6.1.34 Text Alignment

The simple type ST_TextAlignment defines the text alignment. The available options are:

- l – left
- ctr – ctr
- r – right

5.15.6.1.35 Auto Text Rotation

The simple type ST_AutoTextRotation defines the behavior of the text as the containing shape is rotated. The following options are available:

- none – no rotation, the text rotates with the shape
- upr – upright
- grav – gravity

5.15.6.1.36 Grow Direction

The simple type ST_GrowDirection defines the growing behavior of the snake algorithm. The following options are available:

- tL – grow from the top left
- tR – grow from the top right
- bL – grow from the bottom left
- gR – grow from the bottom right

5.15.6.1.37 Flow Direction

The simple type ST_FlowDirection Specifies whether nodes are arranged in rows or columns for the snake algorithm. The following options are available:

- row – Row
- col – column

5.15.6.1.38 Continue Direction

The simple type ST_ContinueDirection specifies the direction of the subsequent row or column in the snake algorithm. The following options are available:

- revDir – reverse direction

- sameDir – same direction

5.15.6.1.39 Breakpoint

The simple type ST_Breakpoint defines the behavior of a snake diagram's breaking behavior. The available options are:

- endCnv – end of canvas
- bal – balanced
- fixed – fixed

5.15.6.1.40 Offset

The simple type ST_Offset defines the behavior of whether each row or column in the snake algorithm is offset from the previous row or column. The available options are:

- ctr – the offset is center based
- off – there is an offset defined

5.15.6.1.41 Hierarchy Alignment

The simple type ST_HierarchyAlignment specifies the relationship between parent and children in a hierarchy diagram. The following options exist:

- tL – top left
- tR – top right
- tCtrCh – top center children
- tCtrDes – top center descendants
- bL – bottom left
- bR – bottom right
- bCtrCh – bottom center children
- bCtrDes – bottom center descendants
- lT – left top
- lB – left bottom
- lCtrCh – left center children
- lCtrDes – left center descendants
- rT – right top
- rB – right bottom
- rCtrCh – right center children
- rCtrDes – right center descendants

5.15.6.2 Variable Type

The simple type ST_VariableType defines the type of the conditional expression. These variables turn user interface options on and off. The available variable types are:

- unknown – Unknown variable type. This can be used by implementing applications to define a variable type outside of the scope of what is defined by this simple type.
- orgChart – organizational chart command
- chMax – used for the insert shape dropdown commands
- chPref – used for the insert shape button
- bulEnabled – used for the insert bullet command
- dir – diagram direction, RTL or LTR
- hierBranch – stores the different layouts for org chart
- animOne – exposes options for animation
- animLvl – exposes options for animation

5.15.6.2.1 Output Shape Type

The simple type ST_OutputShapeType defines special shape types which are unique to diagrams. The unique types are:

- none – none
- conn – connector

5.15.6.3 Diagram Definitions

Diagram definitions define the look of a diagram. They utilize almost all the aspects of the file format discussed thus far in order to create layout properties which get translated into visual diagrams.

There are a few more simple types that need to be defined before talking about the larger aspects of what it takes to create a diagram definition. Many of these simple types are provided as wrappers or lists of the above mentioned simple types.

5.15.6.3.1 Lists

There are a group of simple types which act as lists of the simple types already mentioned. They are all defined in the following general way:

```
<xsd:simpleType name= NAME OF TYPE >
  <xsd:list itemType= NAME OF SIMPLE TYPE />
</xsd:simpleType>
```

The list of these list types are the following simple types:

- ST_AxisTypes – list of ST_AxisType
- ST_ElementTypes – list of ST_ElementType
- ST_Ints – list of xsd:int
- ST_UnsignedInts – list of xsd:unsignedInt
- ST_Booleans – list of xsd:boolean

5.15.6.3.2 Function Value

The simple type ST_FunctionValue is a value for a condition expression. It is defined as:

```
<xsd:simpleType name="ST_FunctionValue" final="restriction">
  <xsd:union memberTypes="xsd:int xsd:boolean ST_Direction
    ST_HierBranchStyle ST_AnimOneStr ST_AnimLvlStr" />
</xsd:simpleType>
```

5.15.6.3.3 Direction

The simple type ST_Direction defines the direction the diagram is to be laid out. The directions available are:

- norm – normal
- rev – reversed

5.15.6.3.4 Hierarchy Branch Style

The simple type ST_HierBranchStyle changes the behavior of the branch style in hierarchy, or org chart, diagrams. This value can be modified by a user directly from the user interface. The different types of branch styles are:

- l – left
- r – right
- hang – hanging
- std – standard
- init – initial

5.15.6.3.5 One by One Animation

The simple type ST_AnimOneStr allows for differentiation in the way a one-by-one animation is displayed in the user interface. The following options are available:

- none – nothing is displayed
- one – the term one-by-one is used
- branch – the term branch one-by-one is used to distinguish a hierarchy diagram

5.15.6.3.6 Level Animation

The simple type ST_AnimLvlStr acts very much like the type ST_AminOneStr, as it allows for two different descriptions of a single animation depending upon the desired behavior for a particular diagram. The following allows for differentiation of radial diagrams. The different options are:

- none – nothing
- lvl – normal depth first traversal
- ctr – allows a radial diagram to be shown with the center node first

5.15.6.3.7 Org Chart Flag

The complex type CT_OrgChart defines that the diagram will be an organizational chart. Organizational charts contain special behavior in that assistants can now be utilized correctly. The complex type is defined as follows:

```
<xsd:complexType name="CT_OrgChart">
  <xsd:attribute name="val" type="xsd:boolean" default="false"
    use="optional" />
</xsd:complexType>
```

5.15.6.3.8 Node Count

The simple type ST_NodeCount holds a value that is used by the complex types CT_ChildMax and CT_ChildPref.

5.15.6.3.9 Child Max

This complex type defines when the user interface for inserting a child shape is to become disabled for a given node, or rather the max number of children that the user interface will be enabled for. This complex type is defined as:

```
<xsd:complexType name="CT_ChildMax">
  <xsd:attribute name="val" type="ST_NodeCount" default="-1"
    use="optional" />
</xsd:complexType>
```

5.15.6.3.10 Child Preference

This complex type defines how many children are inserted with a single action through the user interface to add a child. This is useful in hierarchy diagrams in which one would like to specify that every shape should have three children. A single click of the add shape button would add three children. The complex type is defined as follows:

```
<xsd:complexType name="CT_ChildPref">
  <xsd:attribute name="val" type="ST_NodeCount" default="-1"
    use="optional" />
</xsd:complexType>
```

5.15.6.3.11 Bullets Enabled

This complex type defines if the user interface for inserting a bullet into a shape is enabled or disabled for a given node. The complex type is defined as follows:

```
<xsd:complexType name="CT_BulletEnabled">
  <xsd:attribute name="val" type="xsd:boolean" default="false"
    use="optional" />
</xsd:complexType>
```

5.15.6.3.12 Direction

This complex type defines the direction of the diagram, be it normal or reversed. The complex type is defined as:

```
<xsd:complexType name="CT_Direction">
  <xsd:attribute name="val" type="ST_Direction" default="norm"
    use="optional" />
</xsd:complexType>
```

5.15.6.3.13 Hierarchy Branch Style

This complex type defines the hierarchy branch style for a diagram. The complex type is defined as:

```
<xsd:complexType name="CT_HierBranchStyle">
  <xsd:attribute name="val" type="ST_HierBranchStyle" default="std"
    use="optional" />
</xsd:complexType>
```

5.15.6.3.14 Animate as One

This complex type defines the animate as one value for a diagram. The complex type is defined as:

```
<xsd:complexType name="CT_AnimOne" >
  <xsd:attribute name="val" type="ST_AnimOneStr" default="one"
    use="optional" />
</xsd:complexType>
```

5.15.6.3.15 Animate by Level

This complex type defines the animate by level value for a diagram. The complex type is defined as:

```
<xsd:complexType name="CT_AnimLvl">
  <xsd:attribute name="val" type="ST_AnimLvlStr" default="none"
    use="optional" />
</xsd:complexType>
```

5.15.6.3.16 Layout Property Set

The complex type CT_LayoutPropertySet holds all of the layout properties for a given diagram. The layout property set is a single structure which contains most of what has been talked about thus far in a diagram definition. The layout property set is defined as:

```
<xsd:complexType name="CT_LayoutVariablePropertySet">
  <xsd:sequence>
    <xsd:element name="orgChart" type="CT_OrgChart"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="chMax" type="CT_ChildMax" minOccurs="0"
      maxOccurs="1" />
```

```
      <xsd:element name="chPref" type="CT_ChildPref"
        minOccurs="0" maxOccurs="1" />
      <xsd:element name="bulletEnabled" type="CT_BulletEnabled"
        minOccurs="0" maxOccurs="1" />
      <xsd:element name="dir" type="CT_Direction" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="hierBranch" type="CT_HierBranchStyle"
        minOccurs="0" maxOccurs="1" />
      <xsd:element name="animOne" type="CT_AnimOne" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="animLvltype="CT_AnimLvl" minOccurs="0"
        maxOccurs="1" />
    </xsd:sequence>
  </xsd:complexType>
```

Because all of the contents of this complex type have already been discussed, no further detail on this complex type needs to be given.

5.15.6.3.17 Iterators

The attribute group AG_IteratorAttributes defines the attributes used by the iterators forEach, presOf, and if. The attribute group is defined as follows:

```
  <xsd:attributeGroup name="AG_IteratorAttributes">
    <xsd:attribute name="axis" type="ST_AxisTypes" use="optional"
      default="none" />
    <xsd:attribute name="ptType" type="ST_ElementTypes"
      use="optional" default="all" />
    <xsd:attribute name="hideLastTrans" type="ST_Booleans"
      use="optional" default="true" />
    <xsd:attribute name="st" type="ST_Ints" use="optional" default="1" />
    <xsd:attribute name="cnt" type="ST_UnsignedInts" use="optional"
      default="0" />
    <xsd:attribute name="step" type="ST_Ints" use="optional" default="1" />
  </xsd:attributeGroup>
```

5.15.6.3.18 Constraints

The attribute group AG_ConstraintAttributes defines the attributes used to specify a constraint. The attribute group is defined as:

```
  <xsd:attributeGroup name="AG_ConstraintAttributes">
    <xsd:attribute name="type" type="ST_ConstraintType" use="required" />
    <xsd:attribute name="for" type="ST_ConstraintRelationship"
      use="optional" default="self" />
    <xsd:attribute name="forName" type="xsd:IDREF" use="optional" />
```

```
    <xsd:attribute name="ptType" type="ST_ElementType" use="optional"
      default="all" />
  </xsd:attributeGroup>
```

5.15.6.3.19 Constraint References

The attribute group AG_ConstraintRefAttributes defines the attributes used to specify a constraint reference. The attribute group is defined as:

```
  <xsd:attributeGroup name="AG_ConstraintRefAttributes">
    <xsd:attribute name="refType" type="ST_ConstraintType"
      use="optional" default="unknown" />
    <xsd:attribute name="refFor" type="ST_ConstraintRelationship"
      use="optional" default="self" />
    <xsd:attribute name="refForName" type="xsd:IDREF"
      use="optional" />
    <xsd:attribute name="refPtType" type="ST_ElementType"
      use="optional" default="all" />
  </xsd:attributeGroup>
```

5.15.6.3.20 Constraint

The complex type CT_Constraint define a constraint within the layout framework. A constraint acts as a limit or sets a value to a given parameter in a diagram definition, for example, it can be used to specify that all nodes of a give point type are the same size. A constraint is defined as:

```
  <xsd:complexType name="CT_Constraint">
    <xsd:attributeGroup ref="AG_ConstraintAttributes" />
    <xsd:attributeGroup ref="AG_ConstraintRefAttributes" />
    <xsd:attribute name="op" type="ST_BoolOperator" use="optional"
      default="none" />
    <xsd:attribute name="val" type="xsd:double" use="optional"
      default="0" />
    <xsd:attribute name="fact" type="xsd:double" use="optional"
      default="1" />
  </xsd:complexType>
```

5.15.6.3.21 Constraint List

The complex type CT_Constraints is a sequence of CT_Constraint complex types. It is defined as:

```
  <xsd:complexType name="CT_Constraints">
    <xsd:sequence>
      <xsd:element name="constr" type="CT_Constraint" minOccurs="0"
        maxOccurs="unbounded" />
    </xsd:sequence>
  </xsd:complexType>
```

5.15.6.3.22 Rule

The complex type CT_NumericRule defines a layout framework constraint rule. Rules are run after the diagram is created in order to specify what happens when the diagram doesn't fully fit within the bounds. This allows for specific behavior to be defined rather than using default rules for fitting the diagram. A rule is defined in the following way:

```
<xsd:complexType name="CT_NumericRule" >
  <xsd:attributeGroup ref="AG_ConstraintAttributes" />
  <xsd:attribute name="val" type="xsd:double" use="optional"
    default="NaN" />
  <xsd:attribute name="fact" type="xsd:double" use="optional"
    default="NaN" />
  <xsd:attribute name="max" type="xsd:double" use="optional"
    default="NaN" />
</xsd:complexType>
```

5.15.6.3.23 Rule List

The complex type CT_Rules is simply a list of CT_NumericRule complex types. It is defined in the following manner:

```
<xsd:complexType name="CT_Rules">
  <xsd:sequence>
    <xsd:element name="rule" type="CT_NumericRule"
      minOccurs="0" maxOccurs="unbounded" />
  </xsd:sequence>
</xsd:complexType>
```

5.15.6.3.24 Presentation Of

The complex type CT_PresentationOf defines the mapping between data and the diagram. The complex type is defined in the following manner:

```
<xsd:complexType name="CT_PresentationOf">
  <xsd:attributeGroup ref="AG_IteratorAttributes" />
</xsd:complexType>
```

5.15.6.3.25 Layout Shape

The simple type ST_LayoutShapeType is a simple type that contains all of the shapes available which can be used within a diagram. The simple type is defined as a union of ST_OutputShapeType and an externally defined ST_ShapeType.

5.15.6.3.26 Index1

The simple type ST_Index1 defines a 1-based index that is used to index values elsewhere. The simple type is defined as:

```
<xsd:simpleType name="ST_Index1">
  <xsd:restriction base="xsd:unsignedInt">
    <xsd:minInclusive value="1" />
  </xsd:restriction>
</xsd:simpleType>
```

5.15.6.3.27 Adjust Handle

The complex type CT_Adj specifies a shape adjust handle modification. The shapes within a diagram can be modified based on their adjust handles, for example, the radius of the corner rounding in a rounded rectangle can be adjusted using this complex type. The complex type is defined in the following manner:

```
<xsd:complexType name="CT_Adj">
  <xsd:attribute name="idx" type="ST_Index1" use="required" />
  <xsd:attribute name="val" type="xsd:double" use="required" />
</xsd:complexType>
```

5.15.6.3.28 Adjust Handle List

The complex type CT_AdjLst holds all of the adjust handles for a given shape. The number of adjust handles accessible varies shape by shape, but there are usually less than four for a given shape. The complex type is defined in the following way:

```
<xsd:complexType name="CT_AdjLst" o:cname="CAdjList">
  <xsd:sequence>
    <xsd:element name="adj" type="CT_Adj" minOccurs="0"
      maxOccurs="unbounded" />
  </xsd:sequence>
</xsd:complexType>
```

5.15.6.3.29 Shape

The complex type CT_Shape specifies a shape for a layout node. The shape complex type holds all of the information associated with the particular layout node and all of the adjustments or modifications that can be made to the shape. The rot attribute specifies a rotation on the shape. The blip attribute specifies an image that is used as a background fill for the shape and the blipPhldr attribute specifies whether or not the shape shows up with an image placeholder. The zOrderOff attribute specifies an offset to be used for the z-ordering of this shape, while the lkTxEntry attribute prevents text editing within the shape. A shape is defined in the following manner:

```
<xsd:complexType name="CT_Shape">
  <xsd:sequence>
    <xsd:element name="adjLst" type="CT_AdjLst" minOccurs="0"
      maxOccurs="1" />
  </xsd:sequence>
  <xsd:attribute name="rot" type="xsd:double" use="optional" default="0" />
```

```
    <xsd:attribute name="type" type="ST_LayoutShapeType"
      use="optional" default="none" />
    <xsd:attribute ref="r:blip" use="optional" />
    <xsd:attribute name="zOrderOff" type="xsd:int" use="optional"
      default="0" />
    <xsd:attribute name="hideGeom" type="xsd:boolean" use="optional"
      default="false" />
    <xsd:attribute name="lkTxEntry" type="xsd:boolean" use="optional"
      default="false" />
    <xsd:attribute name="blipPhldr" type="xsd:boolean" use="optional"
      default="false" />
  </xsd:complexType>
```

5.15.6.3.30 Parameter

The complex type CT_Parameter holds the information regarding an algorithm parameter. The complex type is defined as:

```
  <xsd:complexType name="CT_Parameter">
    <xsd:attribute name="type" type="ST_ParameterId" use="required" />
    <xsd:attribute name="val" type="xsd:string" use="required" />
  </xsd:complexType>
```

5.15.6.3.31 Algorithm

The complex type CT_Algorithm defines the algorithm which the diagram will use to layout the nodes which contain the data. Also defined here are the optional list of parameters which are associated with this algorithm and modify its behavior. An algorithm is defined in the following manner:

```
  <xsd:complexType name="CT_Algorithm" >
    <xsd:sequence>
      <xsd:element name="param" type="CT_Parameter" minOccurs="0"
        maxOccurs="unbounded" />
    </xsd:sequence>
    <xsd:attribute name="type" type="ST_AlgorithmType" use="required" />
    <xsd:attribute name="rev" type="xsd:unsignedInt" use="optional"
      default="0" />
  </xsd:complexType>
```

5.15.6.3.32 Layout Node

The complex type CT_LayoutNode is the main building block of a diagram. A layout node contains enough information to lay out itself and its children. The name attribute is simply a unique string given to the layout node. The styleLbl attribute references the style label that is used to style the layout node. This style label has already been defined in this document. A layout node is defined in the following manner:

```
<xsd:complexType name="CT_LayoutNode">
  <xsd:choice minOccurs="0" maxOccurs="unbounded">
    <xsd:element name="alg" type="CT_Algorithm" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="shape" type="CT_Shape" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="presOf" type="CT_PresentationOf"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="constrLst" type="CT_Constraints"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="ruleLst" type="CT_Rules" minOccurs="0"
    maxOccurs="1" />
    <xsd:element name="varLst"
      type="CT_LayoutVariablePropertySet" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="forEach" type="CT_ForEach" />
    <xsd:element name="layoutNode" type="CT_LayoutNode" />
    <xsd:element name="choose" type="CT_Choose" />
  </xsd:choice>
  <xsd:attribute name="name" type="xsd:ID" use="optional" />
  <xsd:attribute name="styleLbl" type="xsd:string" use="optional" />
  <xsd:attribute name="chOrder" type="ST_ChildOrderType"
    use="optional" default="b" />
  <xsd:attribute name="moveWith" type="xsd:IDREF" use="optional" />
</xsd:complexType>
```

5.15.6.3.33 For Each

The complex type CT_ForEach defines a for each iterator. The iteration behaves as if it were a for each loop. The complex type is defined as:

```
<xsd:complexType name="CT_ForEach">
  <xsd:choice minOccurs="0" maxOccurs="unbounded">
    <xsd:element name="alg" type="CT_Algorithm" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="shape" type="CT_Shape" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="presOf" type="CT_PresentationOf"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="constrLst" type="CT_Constraints"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="ruleLst" type="CT_Rules" minOccurs="0"
      maxOccurs="1" />
```

```
      <xsd:element name="forEach" type="CT_ForEach" />
      <xsd:element name="layoutNode" type="CT_LayoutNode" />
      <xsd:element name="choose" type="CT_Choose" />
    </xsd:choice>
    <xsd:attribute name="name" type="xsd:ID" use="optional" />
    <xsd:attribute name="ref" type="xsd:IDREF" use="optional" />
    <xsd:attributeGroup ref="AG_IteratorAttributes" />
  </xsd:complexType>
```

5.15.6.3.34 When

The complex type CT_When defines an if conditional expression. The complex type is usually used in conjunction with the else counterpart which is defined next. The CT_When complex type is defined in the following manner:

```
  <xsd:complexType name="CT_When">
    <xsd:choice minOccurs="0" maxOccurs="unbounded">
      <xsd:element name="alg" type="CT_Algorithm" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="shape" type="CT_Shape" minOccurs="0"
        maxOccurs="1" />
      <xsd:element name="presOf" type="CT_PresentationOf"
        minOccurs="0" maxOccurs="1" />
      <xsd:element name="constrLst" type="CT_Constraints"
        minOccurs="0" maxOccurs="1" />
      <xsd:element name="ruleLst" type="CT_Rules" minOccurs="0"
        maxOccurs="1" o:cname="Rules" />
      <xsd:element name="forEach" type="CT_ForEach" />
      <xsd:element name="layoutNode" type="CT_LayoutNode" />
      <xsd:element name="choose" type="CT_Choose" />
    </xsd:choice>
    <xsd:attribute name="name" type="xsd:ID" use="optional" />
    <xsd:attributeGroup ref="AG_IteratorAttributes" />
    <xsd:attribute name="func" type="ST_FunctionType"
      use="required" />
    <xsd:attribute name="arg" type="ST_FunctionArgument"
      use="optional" />
    <xsd:attribute name="op" type="ST_FunctionOperator"
      use="required" />
    <xsd:attribute name="val" type="ST_FunctionValue"
        use="required" />
  </xsd:complexType>
```

5.15.6.3.35 Otherwise

The complex type CT_Otherwise is the else counterpart to the already defined if conditional expression. The complex type is defined as:

```
<xsd:complexType name="CT_Otherwise" o:cname="DDOtherwise">
  <xsd:choice minOccurs="0" maxOccurs="unbounded">
    <xsd:element name="alg" type="CT_Algorithm" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="shape" type="CT_Shape" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="presOf" type="CT_PresentationOf"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="constrLst" type="CT_Constraints"
      minOccurs="0" maxOccurs="1" />
    <xsd:element name="ruleLst" type="CT_Rules" minOccurs="0"
      maxOccurs="1" />
    <xsd:element name="forEach" type="CT_ForEach" />
    <xsd:element name="layoutNode" type="CT_LayoutNode" />
    <xsd:element name="choose" type="CT_Choose" />
  </xsd:choice>
  <xsd:attribute name="name" type="xsd:ID" use="optional" />
</xsd:complexType>
```

5.15.6.3.36 Choose Statement

The complex type CT_Choose packages together the if and else conditions into an actual if/else statement. The complex type is defined in the following manner:

```
<xsd:complexType name="CT_Choose" o:cname="DDChoose">
  <xsd:sequence>
    <xsd:element name="if" type="CT_When" maxOccurs="unbounded" />
    <xsd:element name="else" type="CT_Otherwise" minOccurs="0" />
  </xsd:sequence>
  <xsd:attribute name="name" type="xsd:ID" use="optional" />
</xsd:complexType>
```

5.15.6.3.37 Sample Data

The complex type CT_SampleData defines how the data model is to be populated in an initial manner. The complex type holds a temporary data model when there is no data model present in order to display a diagram on an initial insert. The complex type is defined by:

```
<xsd:complexType name="CT_SampleData">
  <xsd:sequence>
    <xsd:element name="dataModel" type="CT_DataModel" minOccurs="0" />
  </xsd:sequence>
```

```
    <xsd:attribute name="useDef" type="xsd:boolean" use="optional"
      default="false" />
  </xsd:complexType>
```

5.15.6.3.38 Common Structures

CT_Category, CT_Categories, CT_Name, CT_Description, and ST_Version are defined just as their counterparts in the subclauses above, and they perform the same tasks.

5.15.6.3.39 Diagram Definition

The complex type CT_DiagramDefinition is the root element for a diagram definition. It is defined in the following manner:

```
  <xsd:complexType name="CT_DiagramDefinition">
    <xsd:sequence>
      <xsd:element name="title" type="CT_Name" minOccurs="0"
        maxOccurs="unbounded" />
      <xsd:element name="desc" type="CT_Description"
        minOccurs="0" maxOccurs="unbounded" />
      <xsd:element name="catLst" type="CT_Categories" minOccurs="0 />
      <xsd:element name="sampData" type="CT_SampleData" minOccurs="0" />
      <xsd:element name="styleData" type="CT_SampleData" minOccurs="0" />
      <xsd:element name="clrData" type="CT_SampleData" minOccurs="0" />
      <xsd:element name="layoutNode" type="CT_LayoutNode" />
    </xsd:sequence>
    <xsd:attribute name="uniqueId" type="xsd:anyURI" use="optional" />
    <xsd:attribute name="minVer" type="ST_Version" use="optional"
      default="12.0" />
    <xsd:attribute name="defStyle" type="xsd:anyURI" use="optional" />
  </xsd:complexType>
```

6. Introduction to VML

This clause is informative.

This clause contains a detailed introduction to the components of Vector Markup Language (VML).

6.1 Introduction

This section provides an overview of the most common parts of VML. The VML format is a legacy format originally introduced with Office 2000 and is included and fully defined in this specification for backwards compatibility reasons. The DrawingML format is a newer and richer format created with the goal of eventually replacing any uses of VML in the Office Open XML formats. VML should be considered a deprecated format included in Office Open XML for legacy reasons only and new applications that need a file format for drawings are strongly encouraged to use preferentially DrawingML .

VML is an XML-based exchange, editing, and delivery format for high-quality vector graphics. VML facilitates the exchange and subsequent editing of vector graphics between a wide variety of productivity and design applications. VML is based on XML 1.0, which is an open, simple, text-based language for describing structured data. VML also supports other World Wide Web Consortium standards, such as Cascading Style Sheets 2.0 (CSS), which specifies style information and 2-D positioning.

As the VML format is a format provided for backward compatibility, many VML elements are defined in the same `urn:schemas-microsoft-com:vml` namespace that is currently used by millions of documents already using VML. In the documentation this is typically shortened to a v: prefix in the VML tag by defining `xmlns:v="urn:schemas-microsoft-com:vml".` The namespaces used for VML are legacy namespaces. Once again, VML should be considered a deprecated format included in Office Open XML for legacy reasons only and new applications that need a file format for drawings are strongly encouraged to use preferentially DrawingML .

Additional elements and attributes are defined in namespaces that reflect how they are used (all VML namespaces defined in this Standard maintain the legacy namespace structure for backward compatibility):

- urn:schemas-microsoft-com:office:office (office document)
- urn:schemas-microsoft-com:office:word (word-processing document)
- urn:schemas-microsoft-com:office:excel (spreadsheet document)
- urn:schemas-microsoft-com:office:powerpoint (presentation document)

6.2 Shape Element

The Shape element is the basic building block of VML. A shape may exist on its own or within a Group element. Shape defines many attributes and sub-elements that control the look and behavior of the shape. A

shape must define at least a Path and size (Width, Height). VML also uses properties of the CSS2 style attribute to specify positioning and sizing.

Note that this subclause also applies to the set of pre-defined shape primitives provided by the VML elements Arc, Curve, Image, Line, Oval, Polyline, Rect, and RoundRect.

The following attributes are used to define a minimal shape:

Attribute	Description
FillColor	Brush color that fills the closed path of a shape.
Position	Type of positioning used to place an element.
Top	Position of the shape relative to the element above it in the flow of the page.
Left	Position of the shape relative to the element left of it in the document flow.
Width	Width of the shape.
Height	Height of the shape.
Path	Line that makes up the edges of a shape.

The following example creates a minimal shape:

```
<v:shape fillcolor="green"
  style="position:relative;top:1;left:1;width:50;
  height:50" path="m 1,1 l 1,50, 50,50, 50,1 x e">
</v:shape>
```

Although there is no official categorization of the Shape element's attributes or sub-elements, it is useful to think of them in groups. The following sections broadly describe the characteristics of the Shape element. A few fundamental attributes and elements are introduced here. For complete details, see the VML reference in Part 4.

6.2.1 Geometry

The following attributes affect the basic structure or outline of the shape.

Attribute	Description
Adj	Adjustment value used to define values for a formula.
Height*	Height of the shape.
Path	Line that makes up the edges of a shape.
Width*	Width of the shape.

* indicates a CSS2 style property

Element	Description

Element	Description
Callout	Defines a callout for a shape.
Extrusion	Defines an extrusion for a shape.
Path	Defines a path for a shape.
Skew	Defines a skew for a shape.
Stroke	Defines a stroke for a shape.
TextBox	Defines a textbox for a shape.
TextPath	Defines a text path for a shape.

6.2.1.1 Height and Width Attributes

Height and Width may be specified using any of the following units. If no unit is specified, pixels is assumed.

Relative	
em	Height of the element's font
ex	Height of the letter "x"
px	Pixels
%	Percentage

Absolute	
in	Inches
cm	Centimeters
mm	Millimeters
pt	Points
pc	Picas

For example:

```
style="position:relative;top:1;left:1;width:50;height:50"
style="position:relative;top:1;left:1;width:10%;height:10%"
```

6.2.1.2 Path Attribute

The Path attribute contains specially formatted text that describes a set of points and line connections between them that define the shape's outline. The path defined must be closed. A path is begun by specifying `m` and a coordinate. This indicates a moveto the given coordinate. Line segments are drawn using `l` (lineto) and specifying subsequent coordinates. A line is closed with `x` after the closing coordinate. The path is ended with `e`.

For example:

```
path="m 1,1 l 1,50, 50,50, 50,1 x e"
```

This starts at (1,1), draws a line to (1,50), (50,50) and (50,1), where the line is closed and the path ended.

The coordinates specified correspond to relative coordinate space (the size of units in relative space can be set by the CoordSize attribute). The shape's actual size is determined by the Height and Width attributes.

For example:

```
<v:shape style="position:relative;top:1;left:1;width:5000;
  height:5000" fillcolor="teal"
  path="m 1,1 l 1,10 10,10 10,1 1,1 x e" />
```

```
<v:shape  style="position:relative;top:1;left:1;width:2500;
  height:2500" fillcolor="teal"
  path="m 1,1 l 1,10 10,10 10,1 1,1 x e" />
```

More than one closed line path may be specified in the Path attribute and each closed region is filled.

```
<v:shape  style="position:relative;top:1;left:1;width:5000;
  height:5000" fillcolor="teal"
  path="m 1,1 l 1,10 10,10 10,1 1,1 x m 20,20 l 20,40 40,40
  40,20 20,20 x e" />
```

The optional Path element, which allows for the creation of more complex paths and regions, overrides the Path attribute if it is specified.

6.2.2 Placement

These attributes affect the layout and placement of shapes. Placement may be defined relative to other shapes or non-VML content that also exists in the container holding the shape.

Attribute	Description
AllowOverlap	Determines if a shape can overlap other shapes.
CoordOrigin	Specifies the coordinate unit origin of the rectangle that bounds a shape.
CoordSize	Specifies the horizontal and vertical units of the rectangle that bounds a shape.
Flip*	Switches the orientation of a shape.
Left*	Determines the position of the shape relative to the element left of it in the document flow.
Margin-Bottom*	Specifies the bottom edge of the shape's containing rectangle relative to the shape anchor.
Margin-Left*	Specifies the left edge of the shape's containing rectangle relative to the shape anchor.

Attribute	Description
Margin-Right*	Specifies the right edge of the shape's containing rectangle relative to the shape anchor.
Margin-Top*	Specifies the top edge of the shape's containing rectangle relative to the shape anchor.
MSO-Position-Horizontal*	Specifies the horizontal positioning data for objects in WordprocessingML.
MSO-Position-Horizontal-Relative*	Specifies relative horizontal position data for objects in WordprocessingML.
MSO-Position-Vertical*	Specifies the vertical position data for objects in WordprocessingML.
MSO-Position-Vertical-Relative*	Specifies relative vertical position data for objects in WordprocessingML.
MSO-Wrap-Distance-Bottom*	Defines the distance from the bottom side of the shape to the text that wraps around it.
MSO-Wrap-Distance-Left*	Defines the distance from the left side of the shape to the text that wraps around it.
MSO-Wrap-Distance-Right*	Defines the distance from the right side of the shape to the text that wraps around it.
MSO-Wrap-Distance-Top*	Defines the distance from the shape top to the text that wraps around it.
MSO-Wrap-Edited*	Determines whether the wrap coordinates were customized by the user.
MSO-Wrap-Mode*	Defines the wrapping mode for text.
Position*	Defines the type of positioning used to place an element.
RelativePosition	Defines a relative position for an object.
Rotation*	Defines the angle that a shape is rotated.
Top*	Defines the position of the shape relative to the element above it in the flow of the page.
Z-Index*	Determines the display order of overlapping shapes.

* indicates a CSS2 style property

6.2.2.1 CoordOrigin and CoordSize Attributes

These attributes define the relative coordinate space of a shape. This space is scaled up or down to match the specified Width and Height of the shape. Coordinates in the Path attribute (or element) are relative to the space defined by CoordOrigin and CoordSize, so the Path definition never needs to change simply to scale the shape.

CoordSize defines the “width” and “height” of the local coordinate space. CoordOrigin defines the top-left coordinate of this space.

For example:

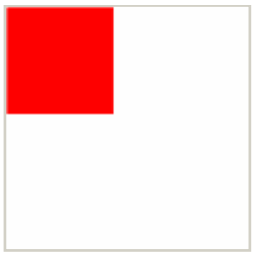
```
coordorigin="0,0"
coordsize="200,200"
```
Extents of local space are (0,0) to (200,200)

```
coordorigin="-100,-100"
coordsize="200,200"
```
Extents of local space are (-100,-100) to (100,100)

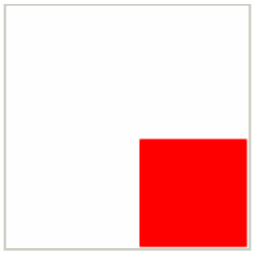
This local space definition affects the position of the shape. Changing the CoordOrigin translates the shape within the local space. Changing the CoordSize affects the size of the shape by changing the size of the local space relative to the shape’s Width and Height.

For example:

```
coordorigin="0,0"
coordsize="500,500"
style="position:absolute;top:0;left:0;width:100pt;
  height:100pt"
```



```
coordorigin="-250,-250"
coordsize="500,500"
style="position:absolute;top:0;left:0;width:100pt;
  height:100pt"
```



```
coordorigin="0,0"
coordsize="250,250"
style="position:absolute;top:0;left:0;width:100pt;
height:100pt"
```

6.2.2.2 Position Attribute

Position can be specified as “static”, “relative” or “absolute”. Static positioning keeps the shape inline with the current flow of the surrounding content – the Top and Left attributes are ignored. Relative uses the Top and

Left attributes to position the shape relative to its position in the current flow. Absolute uses the Top and Left attributes to position the shape with respect to its container.

6.2.3 Formatting

These attributes and elements affect the fill and line properties of the shape.

Attribute	Description
BorderBottomColor	Bottom border color of an inline shape.
BorderLeftColor	Left border color of an inline shape.
BorderRightColor	Right border color of an inline shape.
BorderTopColor	Top border color of an inline shape.
BWMode	Determines how a shape will render for black-and-white output devices.
BWNormal	Defines the black-and-white mode for normal black-and-white output devices.
BWPure	Defines the black-and-white mode for pure black-and-white output devices.
Chromakey	Defines a color that will be transparent and show anything behind the shape.
FillColor	Defines the brush color that fills the closed path of a shape.
Filled	Determines whether the closed path will be filled.
ForceDash	Determines whether a dashed outline is used to draw a shape when a shape has no line or fill.
HR	Specifies that a shape is a horizontal rule.
HRAlign	Defines the alignment of a horizontal rule.
HRHeight	Defines the thickness of a horizontal rule.
HRNoShade	Determines whether a horizontal rule will be displayed with 3-D shading.
HRPct	Defines the length of a horizontal rule as a percentage of page width.
HRStd	Determines whether a shape is a standard horizontal rule.
HRWidth	Defines the length of a horizontal rule.
StrokeColor	Defines the brush color that strokes the path of a shape.
Stroked	Defines whether the path will be stroked.
StrokeWeight	Defines the brush thickness that strokes the path of a shape.

Element	Description
Fill	Defines a fill for a shape.
Imagedata	Defines image data for a shape.
Shadow	Defines a shadow for a shape.

6.2.4 Other

These are miscellaneous attributes and elements.

Attribute	Description
Alt	Defines alternative text to be displayed instead of a graphic.
AllowInCell	Determines whether a shape can be placed in a table.
Bullet	Determines whether a shape is a graphical bullet.
Button	Determines whether a shape will be processed as a button.
Class	Refers to a definition of a CSS style.
ConnectorType	Indicates the type of connector used for joining shapes.
DoubleClickNotify	Sends an event message when a shape is double-clicked.
HRef	Defines a URL for a shape. When the shape is clicked, the browser will load the URL.
ID	Provides a unique identifier for an element.
InsetMode	Specifies whether the host calculates the internal text margin instead of using the inset attribute of the textbox element.
OLE	Specifies whether the shape is an embedded OLE object.
OLEIcon	Determines whether an OLE object will be displayed as an icon.
OnEd	Determines whether the extra handles of a shape are hidden.
OnMouseOver	Triggers a mouse event for a shape.
PreferRelative	Determines whether the original size of an object is saved after reformatting.
Print	Determines whether the shape will be printed.
ReGroupID	Defines a previous group for a shape.
RuleInitiator	Determines whether a rules engine will be used.
RuleProxy	Determines whether a proxy for the rules engine will be used.
Spt	Defines a number used to identify types of shapes.
TableLimits	List of minimum height values for each row in a table.
TableProperties	Determines table properties.
Target	Defines a frame or window that a URL will be displayed in.
Title	Defines the text displayed when the mouse pointer moves over the shape.
Type	Defines a reference to the ID of a ShapeType element.
UserDrawn	Determines whether the user has added the shape to a master slide.
UserHidden	Determines whether a script anchor is hidden.
Visibility	Determines whether a shape is displayed.
WrapCoords	Defines the bounding polygon that surrounds a shape.

1

Element	Description
Formulas	Defines formulas for a shape.

Element	Description
Handles	Defines handles for a shape.
Locks	Defines a lock for a shape.

6.3 Group Element

The Group element is used to collect multiple objects so they can be positioned and transformed as a single unit. Objects that reference their parent container's coordinate space become relative to the group's local space when inserted into a group. Using groups supports creation of complex shapes, composed of many sub-shapes, that can be treated as a single entity.

Group supports a subset of the Shape element's attributes.

Attribute			
AllowInCell	Class	HRPct	Style
AllowOverlap	CoordOrig	HRStd	TableLimits
Alt	CoordSize	HRWidth	TableProperties
BorderBottomColor	DoubleClickNotify	ID	Target
BorderLeftColor	HR	OnEd	Title
BorderRightColor	HRAlign	OnMouseOver	UserDrawn
BorderTopColor	HRef	Print	UserHidden
Bullet	HRHeight	ReGroupID	WrapCoords
Button	HRNoShade	RelativePosition	

The following elements are valid inside a Group:

Element			
Arc	Image	Polyline	Shape
Curve	Line	Rect	ShapeType
Group	Oval	RoundRect	

6.4 ShapeType Element

The ShapeType element defines a definition, or template, for a shape. Such a template is "instantiated" by creating a Shape element that references the ShapeType. The shape can override any value specified by its ShapeType, or define attributes and elements the ShapeType does not provide. A ShapeType may not reference another ShapeType.

The attributes and elements a ShapeType uses are identical to those of the Shape element, with these exceptions.

ShapeType may not use the Type element.

CSS positioning attributes are ignored and not passed to individual Shape instances.

Visibility is always hidden.

A VML authoring agent may make the ShapeType visible, in which case the CSS positioning attributes are meaningful.

The ShapeType element is used to define a shape once and reference it multiple times throughout a document. One of the most useful attributes or elements a ShapeType defines is a complex Path. Since Path coordinates are defined in a relative coordinate space that scales with a shape's height and width, this is very flexible for defining a shape outline that can be custom scaled and formatted for a given use.

6.5 VML Usage in the Office Open XML Format

6.5.1 OfficeArt Shapes

WordprocessingML takes advantage of the template-based shape definition VML provides. This example shows how the two shapes in the screenshot below are created.

The star is first defined using a ShapeType.

```
<v:shapetype id="_x0000_t12" coordsize="21600,21600" o:spt="12"
  path="m10800,l8280,8259,,8259r6720,5146l4200,21600r6600,
  -5019l17400,21600,14880,13405,21600,8259r-8280,xe">
  <v:stroke joinstyle="miter" />
  <v:path gradientshapeok="t" o:connecttype="custom"
…
  o:connectlocs="10800,0;0,8259;4200,21600;17400,21600;21600,8259"
    textboxrect="6720,8259,14880,15628" />
</v:shapetype>
```

The first star is created by referencing the ShapeType via the Type attribute. It sets its own positioning and scaling.

```
<v:shape id="_x0000_s1026" type="#_x0000_t12"
  style="position:absolute;margin-left:33pt;margin-top:25.5pt;
  width:47.25pt;height:47.25pt;z-index:251656704" />
```

The second star is created by referencing the ShapeType and providing its own positioning, scaling and formatting.

```
<v:shape id="_x0000_s1027" type="#_x0000_t12"
  style="position:absolute;margin-left:145.5pt;margin-top:25.5pt;
  width:47.25pt;height:47.25pt;z-index:251657728"
  fillcolor="#4f81bd [3204]" strokecolor="#f2f2f2 [3041]"
  strokeweight="3pt">
  <v:shadow on="t" type="perspective" color="#27405e [1604]"
    opacity=".5" offset="1pt" offset2="-1pt" />
</v:shape>
```

The example contains only the two star shapes. What follows is the entire document:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
<w:document "…">
<w:body>
  <w:p>
    <w:r w:rsidR="00496863">
      <w:rPr>
        <w:noProof />
      </w:rPr>
      <w:pict>
      <v:shapetype id="_x0000_t12" coordsize="21600,21600"
        o:spt="12"
        path="m10800,l8280,8259,,8259r6720,5146l4200,21600r6600,
        -5019l17400,21600,14880,13405,21600,8259r-8280,xe">
        <v:stroke joinstyle="miter" />
        <v:path gradientshapeok="t" o:connecttype="custom"
          o:connectlocs="10800,0;0,8259;4200,21600;
          17400,21600;21600,8259"

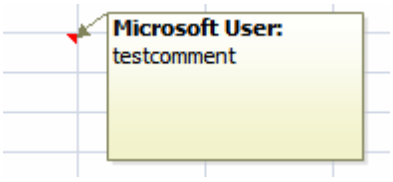
  </w:sectPr>
</w:body>
</w:document>
```

6.5.2 SpreadsheetML Comments

The visible box shown for comments attached to cells is persisted using VML. The comment contents are stored separately as part of SpreadsheetML.



The package item xl/worksheets/sheet1.xml contains the following reference:

```
<legacyDrawing r:id="rId1" />
```

This is a relationship defined in xl/worksheets/_rels/sheet1.xml.rels:

```
<Relationship Id="rId1" Type="…/legacyDrawing"
  Target="../drawings/legacyDrawing1.vml" />
```

The package item xl/drawings/legacyDrawing1.vml defines the yellow gradient rectangle. Again, note that the basic rectangle is defined using a ShapeType. This is reused if multiple comments exist.

```
<xml "…">
  <o:shapelayout v:ext="edit">
    <o:idmap v:ext="edit" data="1" />
  </o:shapelayout>
  <v:shapetype id="_x0000_t202" coordsize="21600,21600" o:spt="202"
    path="m,l,21600r21600,l21600,xe">
    <v:stroke joinstyle="miter" />
    <v:path gradientshapeok="t" o:connecttype="rect" />
  </v:shapetype>
  <v:shape id="_x0000_s1027" type="#_x0000_t202"
    style="position:absolute;
    margin-left:107.25pt;margin-top:52.5pt;width:96pt;height:55.5pt;
    z-index:1" fillcolor="#f2f3cb" strokecolor="#81835a"
    o:insetmode="auto">
    <v:fill color2="#fefefb" type="gradient">
      <o:fill v:ext="view" type="gradientUnscaled" />
    </v:fill>
    <v:shadow on="t" color="silver" opacity=".5" obscured="t" />
    <v:path o:connecttype="none" />
    <v:textbox style="mso-direction-alt:auto">
      <div style="text-align:left" />
    </v:textbox>
    <x:ClientData ObjectType="Note">
      <x:MoveWithCells />
      <x:SizeWithCells />
        <x:Anchor>2, 15, 3, 10, 4, 15, 7, 4</x:Anchor>
      <x:AutoFill>False</x:AutoFill>
      <x:Row>4</x:Row>
      <x:Column>1</x:Column>
      <x:Visible />
    </x:ClientData>
  </v:shape>
</xml>
```

6.5.3 WordprocessingML Text Box

WordprocessingML stores all textbox geometry using VML. This example shows how a simple text box is stored.

All the VML is embedded directly in the word/document.xml file as it is intermingled with other XML. VML is used to define the graphic content. Within the VML textbox tag, additional information about the text box text is added. The following is the section of the document.xml that defines the text box.

```
<w:r w:rsidR="00735D93">
  <w:rPr>
    <w:noProof />
  </w:rPr>
  <w:pict>
    <v:roundrect id="_x0000_s1027" style="position:absolute;
      margin-left:193.2pt;margin-top:-18pt;width:385.75pt;
      height:36.5pt;z-index:251660288;mso-width-percent:900;
      mso-position-horizontal-relative:page;
      mso-position-vertical-relative:margin;mso-width-percent:900;
      mso-width-relative:margin" arcsize="2543f" o:allowincell="f"
      stroked="f">
      <v:shadow on="t" type="perspective" color="#4f81bd [3204]"
        origin="-.5,-.5" offset="-3pt,-3pt" offset2="6pt,6pt"
        matrix=".75,,,.75" />
      <v:textbox style="mso-next-textbox:#_x0000_s1027;
        mso-fit-shape-to-text:t" inset=",,36pt,18pt">
        <w:txbxContent>
          <w:p>
            <w:pPr>
              <w:rPr>
                <w:i />
                <w:color w:val="7F7F7F" w:themeColor="background1"
                  w:themeShade="7F" />
              </w:rPr>
            </w:pPr>
            <w:r w:rsidR="00CA19B3">
              <w:rPr>
                <w:i />
                <w:color w:val="7F7F7F" w:themeColor="background1"
                  w:themeShade="7F" />
              </w:rPr>
              <w:t>Text box</w:t>
            </w:r>
          </w:p>
        </w:txbxContent>
      </v:textbox>
      <w10:wrap type="square" anchorx="page" anchory="margin" />
    </v:roundrect>
```

```
    </w:pict>
  </w:r>
```

This general format is used for any type of textbox, such as those added automatically when a cover page is added to a document.

End of informative text.

7. Introduction to Shared MLs

This clause is informative.

7.1 Math

In this subclause, every mathematical expression is called an *equation*, even if the expression is merely a string of variables or a single object such as a fraction. In XML, an equation is called *OMath*. A Math Paragraph is a group of one or more equations separated by soft carriage returns; that is, they are separate equations that comprise a single paragraph. A Math Paragraph carries its own justification that can be separate from the justification of the paragraph that contains it. Different equations within a Math Paragraph cannot have different types of justification.

Equations can be Display (the only text on the line) or Inline (on a line with text outside of the equation). The Display vs. Inline state is not specified by this standard; instead, a text processor determines how to format Display and Inline equations. Display and Inline equations innately carry different formatting characteristics; Inline equations consume less vertical space so as not to disrupt line spacing with adjacent lines. This means, for example, reducing the size of fractions and n-ary objects that grow.

The following subclauses introduce each of the objects (also called *functions*) that comprise the majority of the Equations schema. As a text processor and not a calculation engine, when converting equations into XML representation, more attention is given to the layout and appearance than to the mathematical meaning of the expressions. That is, $\overrightarrow{abc}\overrightarrow{abc}$ and $\overbrace{abc}\overbrace{abc}$ are represented with the same object, although they carry different mathematical meanings, because both consist of text paired with a stretching character. Similarly, $\frac{n}{k}$ and $\binom{n}{k}$ are represented as the same object. Though mathematically they have different meaning, their layout is similar.

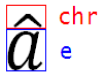
Although the functionality described in this clause is purely about the appearance of equations, other markup defined in this Office Open XML Standard provides independent functionality enabling calculation of mathematical expressions. Formulas in SpreadsheetML (§3.15.1) and Fields in WordprocessingML (§2.17.1) are two examples.

7.1.1 Accent Object

Consider the following letters having diacritical marks:

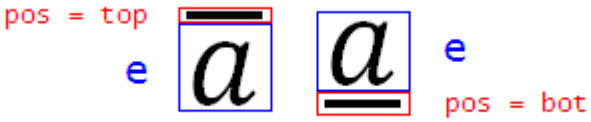
$\dot{a}\ \ddot{a}\ \tilde{a}\ \hat{a}\ \vec{a}$

The accent object is used to represent any baseline text having a combining diacritical mark placed above the base. The accent has only one child, the base element. The accent mark itself is stored as a property. In the examples above, the only difference in the XML representations is the character.



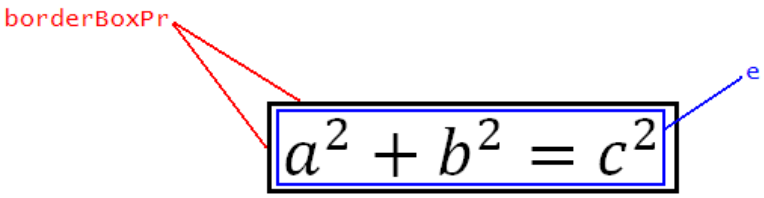
7.1.2 Bar Object

The bar object consists of baseline text with a bar drawn above or below the base. The bar has only one child, the base element. The location of the bar is stored as a property. For example:



7.1.3 Border Box Object

The Border Box object consists of math text—often a formula the author wishes to call out or give special attention—surrounded by a border. Any combination of the edges of the border can be hidden. For example:

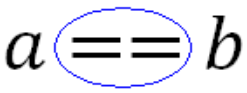


The Border Box can also be used to "cross out" text with a horizontal, vertical, or diagonal (from top-left to bottom-right or from top-right to bottom-left) strikethrough, as follows:

7.1.4 Box Object

The Box object is used to group components of an equation, to apply a single property to everything in the box. The Box serves a number of distinct purposes, including grouping characters to form a single operator (an operator emulator), and thereby inheriting the alignment and manual break properties of operators; grouping a differential such as dx; preventing line breaks from occurring within; and allowing text inside to be reduced in script level.

An example of a Box serving as an operator emulator is:

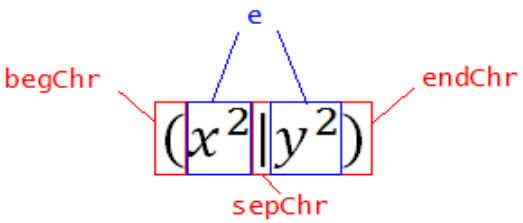


7.1.5 Delimiters

Delimiters consist of opening and closing delimiting characters (such as parentheses, braces, brackets, and vertical bars), and an element contained inside. If two or more elements are contained within delimiters, separating characters are used.

Delimiters can grow to the height of the object they contain. For example, parentheses could grow quite tall to enclose this multi-row matrix: $\begin{pmatrix} 1 & & & & & \\ & 1 & & & & \\ & & 1 & & & \\ & & & 1 & & \\ & & & & 1 & \\ & & & & & 1 \end{pmatrix}$. Or, at the user's discretion, they can maintain their height regardless of the content inside, as in $\left[\frac{a}{b+\frac{c}{d}}\right]$.

Delimiters have a single type of child, the base argument, which can be used multiple times in the object to signify that a separator character is to be used. For example:



If the separator character is not specified in XML, the vertical bar is used.

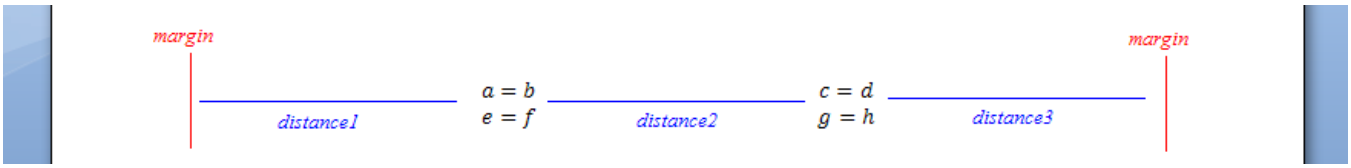
7.1.6 Equation Array Object

The Equation Array object consists of one or more equations grouped as an object. Within the equation array, multiple components can be aligned to each other. Examples of equation arrays are:

$$\begin{aligned} x - y + z &= 10 \\ 3x + y + 2z &= 34 \\ -5x + 2y - z &= -14 \end{aligned}$$ and $$f(x) = \begin{cases} -x, & x < 0 \\ x, & x \geq 0 \end{cases}$$

Equation arrays can have "maximum distribution" such that they occupy the entire width of the column that contains them, as in:

Or, they can have "object distribution" such that there is even spacing between the margin and text (distance1 = distance2 = distance 3):



7.1.7 Fraction Object

The Fraction object consists of a numerator and denominator separated by a fraction bar. The Fraction object is used to classify the different styles of fractions. It is also used to classify the stack object, which places one element above another, with no fraction bar. The four types of fractions are shown below:

Stacked Fraction: $\frac{a}{b}$

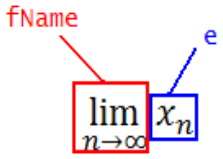
Skewed Fraction: a/b

Linear Fraction: a/b

Stack (noBar) Fraction: $\begin{matrix} n \\ k \end{matrix}$

7.1.8 Function Apply Object

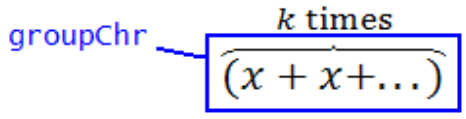
The Function Apply object consists of a function name (or object) applied to a base. The function name, by default, does not use math italics. The Function Apply object consists of a function name (a string or object) and a base element acted upon, as in:



The user can modify the text in a function name, or can add strings to be recognized automatically by the text processor as function names.

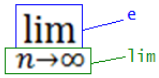
7.1.9 Group Character Object

The Group Character object consists of a character drawn above or below text, often with the purpose of visually grouping items. In the following example, the text above the overbrace is not part of the group character object; it is included only to demonstrate a real-world example of the object in use:



7.1.10 Upper and Lower Limits

Upper Limits and Lower Limits are treated as separate (but similar) objects in the XML representation. Both consist of text on the baseline and reduced-size text immediately above or below it. Examples include:

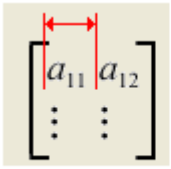


and 
, where in the second example the upper limit is k times and the base is $\overbrace{x+x+\cdots}$.

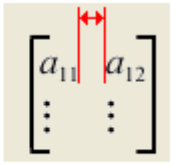
7.1.11 Matrix Object

The Matrix object consists of one or more elements laid out in one or more rows and one or more columns (delimiters not included). Examples include $\begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 5 & 6 \end{pmatrix}$ and $\begin{bmatrix} 1 & \\ & 1 \end{bmatrix}$.

The entire matrix can be aligned, with respect to the surrounding text, at the center, with the top row, or with the bottom row. This property is defined as baseJc. Spacing between columns can be defined using cGp, cGpRule, and cSp. Column Gap refers to the space between the end of one column and the start of the next; column spacing refers to the space between two corresponding edges of adjacent columns.

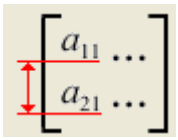


Column Spacing



Column Gap

Row spacing can also be defined using rSp and rSpRule. Row spacing is defined as the distance between baselines on adjacent matrix rows:

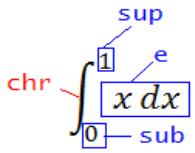


Finally, a matrix can have hidden placeholders (hidePlc). The identity matrix above has hidden placeholders, while the following matrix has placeholders showing: 
7.1.12 N-ary Object

The N-ary object consists of an n-ary object, a base (or operand), and optional upper and lower limits, as in:

$$\int_0^1 x\,dx \qquad \sum_k \binom{n}{k} \qquad \prod_{k=1}^{n} A_k \qquad \bigcup_{n=1}^{m} (X_n \cap Y_n)$$

The components of an n-ary object are as follows:



Other properties of the n-ary object are:

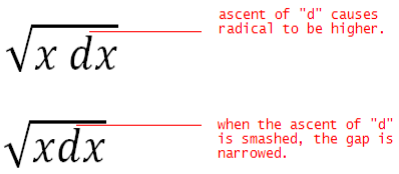
- grow: specifies whether the n-ary object grows to the height of its operand, or stays a fixed height
- limLoc: specifies the placement of n-ary limits: either to the right of the n-ary operator (the subSup position) or centered above and below (the undOvr position).
- supHide: specifies that the upper limit is hidden and no placeholder shows
- subHide: specifies that the upper limit is hidden and no placeholder shows

7.1.13 Phantom Object

The Phantom object allows extra spacing, horizontal, vertical, or both, to be added or suppressed during layout for enhanced appearance.

In the following example, the two radicals are unbalanced: $\sqrt{\frac{a}{b}} = \sqrt{x}$. For enhanced typography, the radical bars and bottom points should line up. To accomplish this, the user should adjust the height of the second radical, to make it the height of the fraction. However, no extra padding should be added to the width. The user can accomplish this by inserting a phantom of the fraction under the second radical, as in: $\sqrt{\frac{a}{b}} = \sqrt{\frac{}{x}}$. In this case, the radicals line up, and the phantom fraction acts as ghost text that adds vertical space but no width (zeroWid). The phantom can also be used to add horizontal space, alone or in conjunction with vertical space.

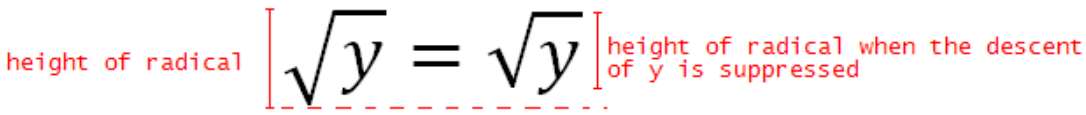
Phantoms are not always invisible. The "smash" is a type of phantom in which the content remains visible. However, part or all of the smash can be ignored during layout of text around it. For example, examine the following two radicals:



A discerning typographer might desire less vertical spacing between the tip of the "d" and the radical bar in the first example. By placing the differential in a smash and assigning it zero height (zeroAsc), the spacing is reduced.

Note that in this same example, when the differential term is placed inside a phantom, the spacing between the first and second characters changes. Again, the discerning typographer wishes that despite the presence of the phantom, differential spacing is retained. By assigning the phantom transparency for spacing (transp), proper spacing is preserved.

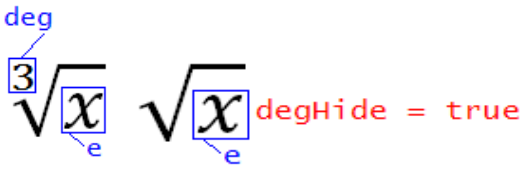
Finally, zeroDesc phantom allows the descent of the phantom base to be ignored during layout. The following example illustrates the usage of zeroDesc:



Each of the phantom properties can be applied whether the phantom is visible or hidden (the show property).

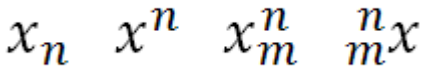
7.1.14 Radical Object

The Radical object consists of a radical, a base e, and an optional degree. When the degree is not shown and a placeholder character is not to appear, the property degHide is used.

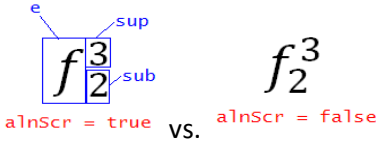


7.1.15 Scripts (Superscript, Subscript, SubSuperscript, PreSubSuperscript)

There are four distinct but related objects that consist of a base and a smaller “script” term either raised or lowered, on the left or right of the base. These are the Subscript, Superscript, SubSuperscript, and PreSubSuperscript:



The SubSuperscript has the option of aligning scripts (alnScr), as in:

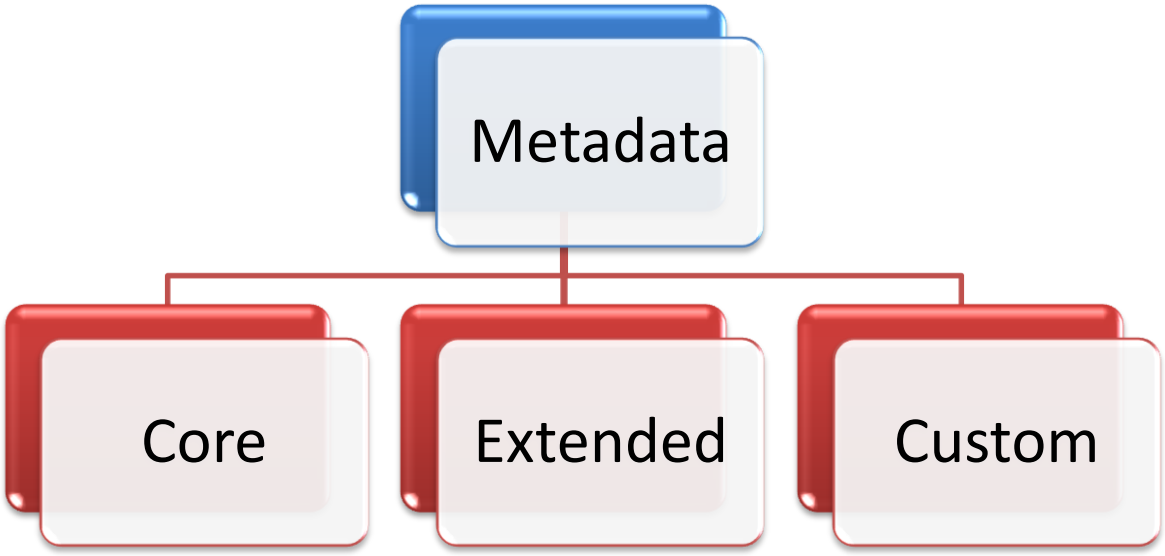


vs.

.

7.2 Metadata

Office Open XML document metadata consists of 43 well-defined properties and user-defined custom properties. Metadata properties are divided into three categories: Core, Extended, and Custom.



Each metadata category is represented by a document part with a corresponding relationship type, content type, and schema. Each metadata property is associated with exactly one metadata part.

The following table lists all well-defined metadata properties:

Property	Category
category	Core
contentStatus	Core
contentType	Core
Created	Core
Creator	Core
description	Core
identifier	Core
keywords	Core
language	Core
lastModifiedBy	Core
lastPrinted	Core
modified	Core

Property	Category

7.2.1 Metadata Properties

Metadata properties are represented as XML elements with associated name and type. There are two types of properties: simple and complex. Simple properties are singular XML elements whose type and value is defined

by the type and value of that XML element. Complex properties contain nested variant type XML elements that define the type and value of complex data such as arrays and vectors. Metadata properties are non-repeatable and must be defined within their associated metadata part. All metadata properties may be empty or omitted. If all properties of a metadata part are omitted, that part may be excluded from the document.

Simple property and custom complex property

```
<dc:creator>John Smith<dc:creator>
<property fmtid="{D5CDD505-2E9C-101B-9397-08002B2CF9AE}" pid="2" name="Editor">
  <vt:lpwstr>John Smith</vt:lpwstr>
</property>
```

7.2.2 Core Properties

Core properties are a predefined set of metadata properties common to all packages, and are discussed in detail in §11 of Part 2 of this Standard: "Open Packaging Conventions".

7.2.3 Extended Properties

Extended properties are a predefined set of metadata properties that are specifically applicable to Office Open XML documents. Extended properties consist of 24 simple properties and 3 complex properties stored in the part targeted by the relationship of type:
http://schemas.openxmlformats.org/officeDocument/2006/relationships/extended-properties.

7.2.4 Custom Properties

Custom properties allow users to extend pre-defined metadata properties with user-defined properties. Custom properties are stored in the part targeted by the relationship of type:
http://schemas.openxmlformats.org/officeDocument/2006/relationships/custom-properties. Each property is represented as a property XML element and uniquely identified through the name, fmtid, and pid attributes. All custom properties are considered complex properties. The type and value of custom properties are specified by its child variant type XML elements.

7.2.5 Variant Types

Office Open XML defines 35 XML elements representing commonly-used variant types to enable the representation and round-tripping of complex data. Variant type XML elements are used as child elements of complex metadata properties to define the type and value.

7.3 Custom XML Data

Within an Office Open XML document, it is sometimes desirable or necessary to store custom XML data (that is, data in a format not defined by this Office Open XML specification) within the contents of the package. To accommodate this need, Office Open XML allows the storage of any arbitrary XML within a package as the target of the http://schemas.openxmlformats.org/officeDocument/2006/relationships/customXml relationship (valid source parts are listed within Part 1 of the Standard).

The following examples illustrate potential uses of this mechanism:

- A document which collects and displays information from a backend data source might want to store the original form of that backend data, so it can be manipulated and uploaded to the original data source at a later date.
- A document author may wish to store additional metadata in an XML format not defined by this Office Open XML specification's existing metadata schemas.
- A document management system may wish to store data tracking the workflow status, retention policies, and so on for this document along with the document.

Once present within a package, this custom XML data shall be maintained as a distinct part separate from the contents of the document, spreadsheet, or presentation. If there are multiple distinct streams of custom XML data, each is maintained as a separate part within the package, so that each can be manipulated independently of all others.

Each Custom XML Data part may also have an implicit relationship to a Custom XML Data Properties part which stores:

- The target namespace of all XML schemas which shall be used to validate the content of the custom XML data part.
- A GUID which shall remain constant over the lifetime of this part (and can therefore be used to uniquely identify it).

7.4 Bibliography

Office Open XML offers functionality to store bibliography entries to permit automatic formatting of citations and bibliographies in the document according to a set of documentation rules defined in an XSLT.

7.4.1 Types of Sources

The Office Open XML formats support a collection of predefined source types for bibliography entries based on the categories most commonly used in various citation and bibliography style guidelines . The set of predefined source types can be extended as needed. The recommended approach for extending this set is to use the `Misc` type, and then leverage the methods described in Part 5 of this standard for extending the format with new attributes or elements. The following types of sources are predefined:

- `Book` (Book)
- `BookSection` (Book Section)
- `JournalArticle` (Journal Article)
- `MagOrNewsArticle` (Magazine or Newspaper Article)
- `ConferenceProceedings` (Conference Proceedings)
- `Report` (Report)
- `SoundRecording` (Sound Recording)
- `Performance` (Performance)
- `Art` (Art)
- `DocumentFromInternetSite` (Document from Internet Site)

- `InternetSite` (Internet Site)
- `Film` (Film)
- `Interview` (Interview)
- `Patent` (Patent)
- `ElectronicSource` (Electronic Source)
- `Case` (Case)
- `Misc` (Miscellaneous)

7.4.2 Child Elements

Each Source element has a number of elements as children, each of which represents a different piece of data for the bibliography entries. For example, a book might have an author, title, publisher, year, and city. Most are self-explanatory, but this document will pay special attention to some of the more complex children.

The child elements are:

- AbbreviatedCaseNumber
- AlbumTitle
- Author
- BookTitle
- Broadcaster
- BroadcastTitle
- CaseNumber
- ChapterNumber
- City
- Comments
- ConferenceName
- Country
- CountryRegion
- Court
- Day
- DayAccessed
- Department
- Distributor
- Edition
- Guid
- Institution
- InternetSiteTitle
- Issue
- JournalName
- LCID
- Medium

- Month
- MonthAccessed
- NumberVolumes
- Pages
- PatentNumber
- PeriodicalTitle
- PlacePublished
- ProductionCompany
- PublicationTitle
- Publisher
- RecordingNumber
- RefOrder
- Reporter
- SourceType
- ShortTitle
- StandardNumber
- StateProvince
- Station
- Tag
- Theater
- ThesisType
- Title
- Type
- URL
- Version
- Volume
- Year
- YearAccessed

An example of the XML defining a source of type `Book` with the title `Office Open XML formats`, and two Authors named `Jones, Brian` and `Davis, Tristan` is:

```
<b:Source>
  <b:Tag>Las07</b:Tag>
  <b:SourceType>Book</b:SourceType>
  <b:Author>
    <b:Author>
      <b:NameList>
        <b:Person>
          <b:Last>Jones</b:Last>
          <b:First>Brian</b:First>
        </b:Person>
```

```
            <b:Person>
              <b:Last>Davis</b:Last>
              <b:First>Tristan</b:First>
            </b:Person>
          </b:NameList>
        </b:Author>
      </b:Author>
      <b:Title>Office Open XML formats</b:Title>
      <b:Year>2007</b:Year>
      <b:City>Trondheim</b:City>
      <b:Publisher>Publisher</b:Publisher>
      <b:Comments>Comments</b:Comments>
      <b:RefOrder>1</b:RefOrder>
      <b:Guid>{DCC25FA1-67CC-4013-B56A-2D42CED7FF0C}</b:Guid>
      <b:LCID>0</b:LCID>
    </b:Source>
```

7.4.3 Author

There are two elements with the same name: Author. The first Author element is a container for the set of contributors attributed to the current source. The second Author element is a child of the first and is used to represent a single contributor. The valid set of contributors is defined as:

- Artist
- Author
- BookAuthor
- Compiler
- Composer
- Conductor
- Counsel
- Director
- Editor
- Interviewee
- Interviewer
- Inventor
- Performer
- ProducerName
- Translator
- Writer

For example, a bibliographic source with an author (Davis, Tristan), editor (Jaeschke, Rex), and translator (Jones, Brian) would be represented by a group of elements representing the three contributors and their specific roles inside an outer Author element, as in:

```
<b:Author>
  <b:Author>
    <b:NameList>

7.4.4 LCID, Guid, Tag, and RefOrder

Four of the child elements for the Source element support important functionality for consuming applications that generate bibliographies using an externally defined stylesheet. The LCID element describes the language to be used when displaying the bibliography entry. This piece of data provides an instruction to the consuming application on the grammar of the citations and bibliography (including international name formats, date formats, and punctuation marks).

The Guid and Tag elements can be leveraged if an application wishes to uniquely identify the bibliography entry described in the Source element. For example, when a Source element is brought into a document and the Tag value for that Source element matches that of another Source element already in the document, the existing Source elements values could be overwritten with the new Source element. Two Source elements with the same Tag element value cannot exist in the same document. GUIDs can then be used in conjunction with Tags to indicate whether a Source element has been edited. When a Source element from one document has been edited, an application may decide to apply the edits to matching Source elements in other documents.

The RefOrder element for a source indicates the position, in numeric sequence, for the first reference to the source within the document text. This information is used in bibliography styles that sort sources by order in the document rather than alphabetical order.

End of informative text.

8. Miscellaneous Topics

This clause is informative.

8.1 Additional Characteristics

Office Open XML provides a way for a producer to provide information to consumers regarding how the data was created and how it should be interpreted. This information is provided by one or more *additional characteristics*.

A producing application has the option of writing out as many or as few additional characteristics as desired.

A consuming application has the option of acting on the additional characteristics or ignoring them

The additional characteristics are stored in a separate XML part, as follows:

```
<additionalCharacteristics>
  <characteristic name='name of characteristic'
    relation='well defined set of relation types'
    val='string' vocabulary='uri'/>
</additionalCharacteristics>
```

For example, consider the case in which `numColumns` is the characteristic name to specify the maximum number of columns supported by the producing SpreadsheetML application, so that the consuming application can understand how to distinguish cell references and variables unambiguously.

The relation attribute specifies the way in which the val attribute should be interpreted. The possible values for relation are: `lt | le | eq | gt | ge`, which mean <, <=, =, >=, >, respectively, and relate to numerical comparison for values and alphabetical comparison for ordering of strings. These relations permit expression of the maximum value, the minimum value, the value, and so on.

The vocabulary attribute is a URI that provides a namespace for the specific characteristic names provided as values of the name attribute. This allows for the creation of a vocabulary of characteristics of interest within a given domain of application without concern for name conflict between vocabularies.

Another example use case would be for a producer to inform the consumer that the computations used to calculate the stored numbers in the SpreadsheetML formulas have a particular numeric precision expressed by the mantissa and exponent. A consumer can optionally check those values to determine whether, for example, the values should be recalculated. The XML to represent these characteristics might look like the following:

```
<additionalCharacteristics>
  <characteristic name='precisionMantissa'
    relation='gt'
    val='-9007199254740992'/>
  <characteristic name='precisionMantissa'
    relation='lt' val='9007199254740992'/>
  <characteristic name='precisionExponent'
    relation='ge' val='-1075'/>
  <characteristic name='precisionExponent'
    relation='le' val='970'/>
</additionalCharacteristics>
```

8.2 Embeddings

Office Open XML provides facilities allowing the embedding of any object within a document. For example, a WordprocessingML document might include data as an embedded SpreadsheetML document rather than a native WordprocessingML table, in order to allow that data to be edited and recalculated by a SpreadsheetML calculation engine, rather than having it stored as a static table of data.

Office Open XML provides for two classes of embedded objects:

- *Embedded Packages* - An embedded Office Open XML document embedded within another Office Open XML document, with both documents stored in the format defined by this Office Open XML specification. For example, a PresentationML document embedded within a SpreadsheetML document results in an embedded package.
- *Embedded Objects* - Any other embedded object data. The data stored in the object shall be identified by a unique string, referred to as its *ProgID*. This string shall be used to determine both the type of data and the application (if any) that shall be used to load and edit the embedded object data.

Office Open XML also allows an image to be optionally associated with the embedded object data, for use when the embedded object application and data itself is not used by the consuming application (e.g. when the object cannot be loaded – the object is from an unknown source; the object is known, but the application has chosen not to load it for performance reasons, and so on).

8.2.1 Embedded Packages

Whenever an Office Open XML document is stored as an embedded object, the embedding shall be referred to as an embedded package. Embedded packages shall be the target of the Embedded Package relationship defined in Part 1: http://schemas.openxmlformats.org/officeDocument/2006/relationships/package. this Office Open XML specification

8.2.2 Embedded Objects

For all other embeddings, the embedded object is stored in an arbitrary format defined by the application whose data is being embedded. These generic embedded objects shall be the target of the Embedded Object relationship: http://schemas.openxmlformats.org/officeDocument/2006/relationships/oleObject. When

parsing the data stored in an embedded object part, an application shall use the associated ProgID (whose location is described in the following subclauses) for the object.

8.2.3 Embeddings in a WordprocessingML Document

When an embedding is stored in a WordprocessingML document, it is stored in one of the following ways:

- In line with text - The object is displayed within the regular text stream (modifying line height and so on to accommodate it).
- Floating – The object is positioned absolutely or relatively within the document and text flow is modified as needed around it.

Each case permits the storage of both the object and the optional VML representation of the image that may be used when the object data is not used by the hosting application as follows:

8.2.3.1 Embeddings In Line With Text

When the embedding is present in line with text, it is stored as follows:

- The WordprocessingML object element specifies the presence of an embedded object in line with text.
- The child Office VML Drawing OLEObject element shall specify the details about the embedding itself, including an explicit relationship to the appropriate Embedded Package or Embedded Object part.
- The child VML shape element shall specify the presence of the image which may be used to represent the object.

For example, if we embed a SpreadsheetML worksheet in a WordprocessingML document, the following run content would be present:

```
<w:r>
  <w:object w:dxaOrig="7247" w:dyaOrig="2920">
    <v:shape id="_x0000_i1026" type="#_x0000_t75"
      style="width:362.25pt;height:146.25pt" o:ole="">
      <v:imagedata r:id="rId6" o:title="" />
    </v:shape>
    <o:OLEObject Type="Embed" ProgID="Excel.Sheet.8"
      ShapeID="_x0000_i1026" DrawAspect="Content" ObjectID="_1218026609"
      r:id="rId7" />
  </w:object>
</w:r>
```

If we examine this markup, it can be seen that:

- We have an inline embedded object, as defined by the object element.
- The OLEObject element specifies that that object is stored as an `Embed`, and that its ProgID is `Excel.Sheet.8` (the ProgID code for Microsoft Excel worksheets); it also specifies that the associated

image (when the object data cannot be used) is stored in the VML shape with a shape ID of `_x0000_i1026`.

- The associated VML shape element with an id attribute value of `_x0000_i1026` shall be used in place of the object whenever it is not loaded - this shape is typically, but is not required to be, stored in the same object element as the OLEObject element. This shape specifies its desired size and provides an explicit relationship to the part that stores the image data.

8.2.3.2 Floating Embeddings

When the embedding is present as a floating object, it is stored as follows:

- The WordprocessingML pict element specifies the presence of a floating image in the document.
- The child Office VML Drawing OLEObject element shall specify the details about the embedding itself, including an explicit relationship to the appropriate Embedded Package or Embedded Object part.
- The child VML shape element shall specify the presence of the image that may be used to represent the object in place of loading the actual object data.

For example, if we embed a SpreadsheetML worksheet in a WordprocessingML document as a floating object, the following run content would be present:

```
<w:r>
  <w:pict>
    <v:shapetype id="_x0000_t75" coordsize="21600,21600" o:spt="75"
      o:preferrelative="t" path="m@4@5l@4@11@9@11@9@5xe" filled="f"
      stroked="f">
      …
    </v:shapetype>
    <v:shape id="_x0000_s1028" type="#_x0000_t75"
      style="position:absolute;margin-left:354.75pt;margin-
      top:642.75pt;width:182.3pt;height:73.6pt;z-index:251660288">
     <v:imagedata r:id="rId4" o:title="" />
    </v:shape>
    <o:OLEObject Type="Embed" ProgID="Excel.Sheet.8"
      ShapeID="_x0000_s1028" DrawAspect="Content" ObjectID="_1218026611"
      r:id="rId5" />
  </w:pict>
</w:r>
```

If we examine this markup, it can be seen that:

- We have a floating image, as defined by the pict element.
- The OLEObject element specifies that that floating image is actually an embedding that is stored as an Embed, and that its ProgID is `Excel.Sheet.8` (the ProgID code for Microsoft Excel worksheets); it also specifies that the associated image (when the object data cannot be used) is stored in the VML shape with a shape ID of `_x0000_s1028`.

- The associated VML shape element with an id attribute value of `_x0000_s1028` shall be used in place of the object whenever it is not loaded - this shape is typically, but is not required to be, stored in the same pict element as the corresponding OLEObject element. This shape specifies its desired size and provides an explicit relationship to the part which stores the image data.

8.2.4 Embeddings in a SpreadsheetML Document

When an embedding is present in a SpreadsheetML document, it shall be stored as follows:

- In the worksheet, the oleObjects element shall store one or more oleObject child elements, one for each embedding within the current worksheet. Each of those oleObject child elements shall also store: an explicit relationship to the associated Embedded Package or Embedded Object part, the ProgID for that embedded object, and (optionally) the last four digits of the shape ID for the associated VML shape. The shape ID itself shall be of the form `_x0000_s####`, where # specifies a single Arabic numeral, in order to be referenced as the alternate image for an embedding in a SpreadsheetML document.
- In the worksheet, the sibling legacyDrawing element shall contain an explicit relationship to the VML Drawing part that (optionally) contains the image data which may be used in place of loading the actual object data.

For example, if we embed a `Contoso Test` object (an example for illustration) in a SpreadsheetML document, the following markup would be stored in the appropriate Sheet part:

```
<s:worksheet>
  …
  <s:legacyDrawing r:id="rId9" />
  <s:oleObjects>
    <s:oleObject progId="Contoso.Test.1" shapeId="1025" r:id="rId5"/>
  </s:oleObjects>
</s:worksheet>
```

If we examine this markup, it can be seen that:

- The oleObject element specifies that we have one embedded object on the worksheet. Its attributes specify that the object is of type `Contoso.Test.1` and that the explicit relationship to the embedded object is `rId5`.
- The sibling legacyDrawing element specifies that the Legacy Drawing part which contains the associated legacy drawing data is contained at the target of the relationship with an ID of `rId9`.
- If we examine the VML Drawing part's contents, we'll see the shape which ends in `1025`, which contains the alternate image for the object:

```
<v:shape id="_x0000_s1025" type="#_x0000_t75" style='position:absolute;
  margin-left:240.75pt;margin-top:105.75pt;width:334.5pt;height:253.5pt;
  z-index:1' filled="t" fillcolor="window [65]" stroked="t"
  strokecolor="windowText [64]" o:insetmode="auto">
  <v:fill color2="window [65]"/>
  <v:imagedata o:relid="rId1" o:title=""/>
  <x:ClientData ObjectType="Pict">
    <x:SizeWithCells/>
    <x:Anchor>5, 1, 7, 1, 11, 63, 23, 19</x:Anchor>
    <x:CF>Pict</x:CF>
  </x:ClientData>
</v:shape>
```

8.2.5 Embeddings in a PresentationML Document

When an embedding is present in a PresentationML document, it shall be stored as follows:

- In the slide, the embedding is stored as a graphic frame using the graphicFrame element in PresentationML.
- The graphicData element for the frame shall have the appropriate URI for its contents: http://schemas.openxmlformats.org/presentationml/2006/ole. Its child element shall be the PresentationML oleObj element, which stores an explicit relationship to the associated Embedded Package or Embedded Object part, the ProgID for that embedded object, and (optionally) the shape ID for the associated VML shape.
- The Slide part shall also have an implicit relationship to a VML Drawing part that (optionally) contains the image data to be used in place of loading the actual object data.

For example, if we embed the `Equation.3` object in a PresentationML document, the following markup would be stored in the shape tree of the appropriate Slide part:

```
<p:graphicFrame>
  …
  <a:graphic>
  C:\Documents and Settings\tristand\Local Settings\Temp\Temporary Directory 4 for
embeddedObject.pptx.zip\ppt\slides\slide1.xml   <a:graphicData
      uri="http://schemas.openxmlformats.org/presentationml/2006/ole">
      <p:oleObj spid="_x0000_s1026" name="Equation" r:id="rId3"
        imgW="320" imgH="272" progId="Equation.3">
        <p:embed />
      </p:oleObj>
    </a:graphicData>
  </a:graphic>
</p:graphicFrame>
```

If we examine this markup, it can be seen that:

- The uri attribute on the graphicData element is http://schemas.openxmlformats.org/presentationml/2006/ole, which dictates that this is an embedded object
- It contains an oleObj element that specifies that the properties of the embedded object. Its attributes specify that the object is of type `Equation.3` and that the explicit relationship to the embedded object is `rId3`.
- The slide may also contain an implicit relationship to a Legacy Drawing part. If we examine the legacy drawing part's contents, the shape with ID `_x0000_s1026` (if present) defines the alternate image:

```
<v:shape id="_x0000_s1026" type="#_x0000_t75" style='position:absolute;
  left:282pt;top:24pt;width:152pt;height:129.25pt'>
  <v:imagedata o:relid="rId1" o:title=""/>
</v:shape>
```

8.3 Future Extensibility

This clause provides a high-level overview of the extensibility model for Office Open XML documents, and a description of packaging conventions in the context of DrawingML and PresentationML. Two main constructs are described: extensibility lists (extLst/ext) and alternate content blocks (AlternateContent).

To illustrate certain points, a number of examples refer to versions of a (fictitious) PresentationML consumer/producer called PML. The 2003 version is called PML 2003; the 2007 version is called PML 2007; and so on.

8.3.1 Terminology

Here are some terms useful when discussing future extensibility.

- *Round tripping* involves the interchange of documents between different consumers/producers, as well as between different versions of the same consumer/producer. The pair of consumers/producers can be on the same or different platforms. Consider the case in which a document is created by the PML 2007. This document is then opened by PML 2003, edited, and saved. The edited document is now opened and used by PML 2007. In this case, the document originally created by PML 2007 has been round-tripped through PML 2003. It is also possible to round-trip a document created by PML 2003 through PML 2007.
- A *Downrev* (or down-level) version of a consumer/producer refers to one that understands an older version of a given schema. An *Uprev* (or up-level) version of a consumer/producer refers to one that understands a newer version of a given schema. The terms Downrev and Uprev are typically used in relative reference to one another. As an example, let's consider again, the two consumer/producer PML 2003 and PML 2007, where PML 2007 was released sometime after PML 2003, and, consequently, PML 2007 understands a newer revision of the DrawingML schema then does PML 2003. PML 2003 is referred to as the Downrev version while PML 2007 is referred to as the Uprev version. It is assumed that the Downrev version has less capability than the Uprev version.

8.3.2 What is Future Extensibility?

The main objective of future extensibility is to design an infrastructure that allows the file format to be extended for representation of data structures in future versions of a given consumer/producer.

On the surface, that isn't hard to do; there could be a special extension bit bucket allocated across every existing schema element, and any future extension could be placed there. However, the problem is more complex than that. The infrastructure must allow document interoperability between current consumers/producers and future consumers/producers, some which have not yet even been designed or built. That is, future extensibility involves building forward compatibility into the document infrastructure while remaining compatible with the current version.

8.3.3 Future Extensibility Requirements

There are three design goals to be considered: visual fidelity, editability, and security.

- *Visual fidelity* involves the desire for users of two consumers/producers to see visually the same thing. This seems like a simple design goal to meet, but, in practice, is not easy to achieve. The difference lies in the capabilities of an Uprev and Downrev consumer/producer. Typically, an Uprev consumer/producer has been extended to have new base capabilities that are not present in the Downrev consumer/producer. As such, the Downrev client does not have the base primitives necessary to express visually the new capability introduced in the Uprev consumer/producer.

  Consider the case in which PML 2007 has the capability to highlight text with a given color, while PML 2003 does not. Given the desire to have PML 2007 documents interoperate with PML 2003, it is necessary for PML 2003 to some way to express visually that text highlight. For example, it might insert a picture of the highlighted text instead of inserting the text itself, since PML 2003 does know how to deal with pictures.
- *Editability* involves the desire for two consumers/producers to be able to edit the same content. Using the highlighted text example from above, despite the fact that PML 2003 and PML 2007 have different capabilities, one would still desire to edit highlighted text a regardless of which version of PML is in use. Again, this becomes difficult when the underlying capabilities of the consumer/producer versions are different.
- *Security* involves the desire to have multiple representations of the same data synchronized. This desire is referred to as security for the reason that out-of-sync representation can have dire consequences. For example, there might be multiple representations for a sensitive piece of information such as a Social Security number. If this piece of information were edited, it would be critical to keep all alternate representations in sync. What if that information were deleted altogether? If only one representation was deleted but others remained, it would be possible for one to have sensitive information in a document when the intent was to have it deleted.

One solution to try to solve the visual fidelity and editability goals is to have two equivalent representations for the same construct. In the highlighted text example above, a picture of the highlighted text (also called a rasterized version of the highlighted text) is an equivalent representation of the highlighted text itself. One

might use the highlighted text representation when the underlying consumer/producer is capable of understanding it; otherwise, the picture version would be used.

Clearly, these design goals compete with each other. While a picture representation of text is capable of capturing full visual fidelity of how extended text looks, obviously that representation doesn't offer the same editability properties of text. One can't manipulate a picture of text nearly as easily as the text itself.

The competing nature of these design characteristics requires that one choose an extensibility construct that offers the best mix of desired characteristics. It will not always be possible to have visual fidelity, editability, and security, at the same time.

8.3.4 Future Extensibility Constructs

The two extensibility constructs used to represent extensions in OOXML schemas are:

8.3.4.1 extLst/ext

The extLst construct is used for straight-up extension of existing schemas of a non-visual nature. The term *straight up* refers to the notion that sometimes extension means refining the semantics of existing constructs. In doing so, an extension sometimes overrides the meaning of previous schemas. extLst and ext were not designed for this scenario. Instead of overriding existing meaning, these two constructs purely augment existing schemas. The nature of the augmentation must be such that it does not overlap any semantics embedded in existing schema constructs.

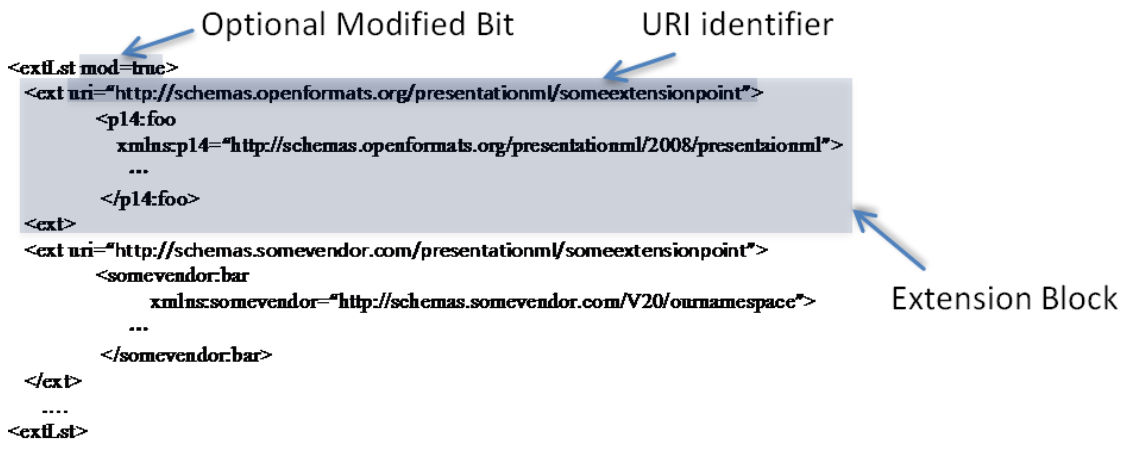
Consider a schema that represents an address, which contain a house number, a street name, a city, a state, and a postal code. An example of a straight-up extension is the addition of a field that describes whether this address is a business or residential location. This is a straight-up extension because the notion of whether an address is business or residential does not conflict with any information that is embedded in the existing schema. Now let's consider the case in which the Postal Service replaces a purely numeric postal code with one that can contain alphanumeric characters. Such a change would not be a straight-up extension because the new representation conflicts with the old representation of the same data, namely the postal code.

Some extensions are visual in nature. An example would be extending a schema to represent text that has been highlighted. By definition, highlighting text is a visual extension. Contrast that to the case of adding a business or residential classification. The latter does not necessarily involve any visual change to the way data is presented.

The extLst and ext constructs are for extensions of a non-visual nature. The main reason their use is limited to this scenario lies in the fact that they do not offer the capability to create alternative representations of the same data.

8.3.4.1.1 extLst/ext Syntax

The extLst and ext construct can be placed only at specific locations within the OOXML schemas. Its syntax is as below:



An extLst is a list of extension blocks that are placed one after the other. Each extension block has an uri attribute, which serves as an identifier to indicate the kind of extension that has been placed here. Upon encountering an extension block, a processing consumer, will determine whether it knows how to process extensions matching that attribute. If the consumer knows how to process such an extension, the markup contained within that extension block is processed. Otherwise, the extension block is preserved so long as the underlying structure being extended by the extLst has not been deleted.

There is no limit to the number of ext extension block constructs. The order of extension blocks can be arbitrary.

An optional modified attribute, mod, is available on extLst. This attribute is set to `true` whenever an edit has occurred at the extended location. Its presence is to aid up-level clients that receive modified documents that have been edited in down-level consumers/producers.

8.3.4.1.2 Round-Trip Behavior of ext Blocks

When extLsts are processed, some consumers/producers will understand some extensions, but not others. The preservation model of ext blocks is that unprocessed extensions are always preserved and retained as long as the underlying schema extended by the structure remains.

8.3.4.1.3 Example

Consider the case in which the notion that each shape can be associated with a given layer, is to be added. The schema for this might look like the following:

```
<p:sld xmlns:a="http://schemas.openxmlformats.org/drawingml/2006/3/main"
       xmlns:r="http://schemas.openxmlformats.org/officeDocument/2006/relationships"
       xmlns:p="http://schemas.openxmlformats.org/presentationml/2006/3/main">
  <p:cSld name="">
    <p:spTree>
      <p:nvGrpSpPr>...
      <p:grpSpPr>...
      <p:sp>
        <p:nvSpPr>
          <p:cNvPr id="3" name="Rectangle 3" descr=""/>
          <p:cNvSpPr/>
          <p:nvPr/>
          <p:extLst mod="false">
            <p:ext uri="http://.../layerExtension">
              <p14:spLayer xmlns:p14="http://schemas.openxmlformats.org/drawingml/2009/3/main" layer="1"/>
            </p:ext>
          </p:extLst>
        </p:nvSpPr>
        <p:spPr>...
        <p:style>...
        <p:txBody>...
      </p:sp>
    </p:spTree>
  </p:cSld>
  <p:clrMapOvr>...
  <p:timing>...
</p:sld>
```

The extLst block is under the non-visual shape properties (i.e., p:nvSpPr). A uri attribute identifies the extension.

Now consider how this markup will be processed by PML 2007 and PML 2009, where PML 2009 is an up-level version of PML 2007.

PML 2007 processes the above markup, and ignores the ext block because it doesn't understand this extension. However, this block will be preserved for any other consumer/producer that may understand it.

PML 2009 processes the above markup, and understands how to deal with layer extensions as indicated by the uri. The spLayer extension is returned, PML 2009 processes the extension and is responsible for writing out any updates to this markup, as required. For example, layer might be changed from 1 to 2.

Note that the extension is a straight-up extension in that layer information is orthogonal to all other non-visual properties, such as the ID, name, and description.

Being non-visual in nature, the information in this extension does not directly affect the appearance of the shape.

8.3.4.2 AlternateContent Blocks

An *alternate content block* allows for an alternative representation of information. In some cases, the desire will be to revise a schema with a newer representation. It will also be common to express visual differences using alternate content blocks. Recall that typically lower-level clients will not have the same capability as their future cousins (i.e., the up level version). As such, any future extension done in the up-level version will need to be expressed in a form that the lower-level version can understand. Hence, the need for alternate representations.

8.3.4.2.1 AlternateContent Syntax

```
<AlternateContent>
  <Choice Requires="namespacefoo">
    <Somemarkup/>
  <Choice Requires="namespacefoo namespacefoobar">
    <Somealternatemarkup/>
  <Fallback>
    <Choiceoflastresort/>
</AlternateContent>
```

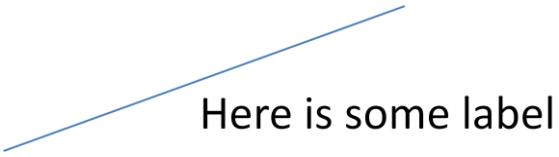
The AlternateContent element and its children, Choice and Fallback, are used to provide alternates for specified content. Each Choice element is examined in turn. The Requires attribute specifies a set of space-delimited namespaces that must be understood in order to select that choice. If there is a match between required namespaces and what the consumer understands, the appropriate Choice is returned. If there are multiple possible matches, only the first match is returned. An optional Fallback element can be used, and is utilized as a default when no match occurs.

8.3.4.2.2 Example

Using PML 2007 and PML 2009, let's assume that PML 2007 understands some current schema version while PML 2009 will understand some future extended version of the current schema.

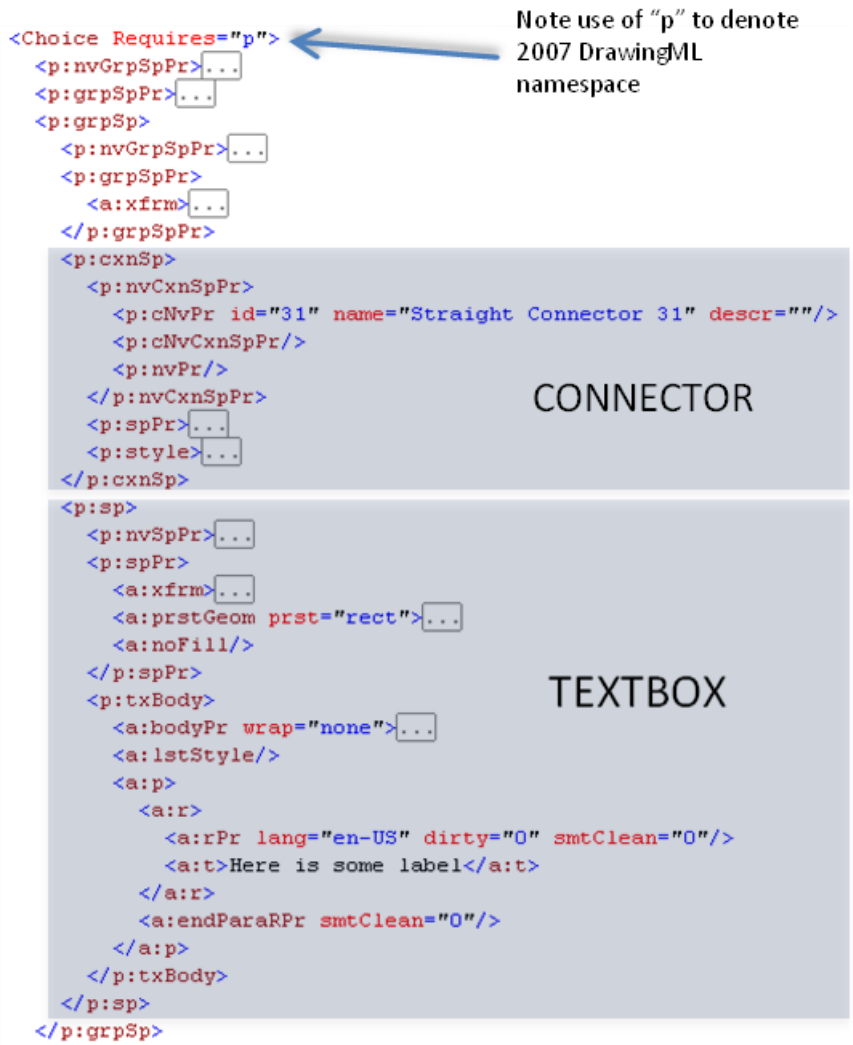
PML 2007 knows how to handle connectors:

Now let's suppose that we desire to add a notion of labels on connectors:



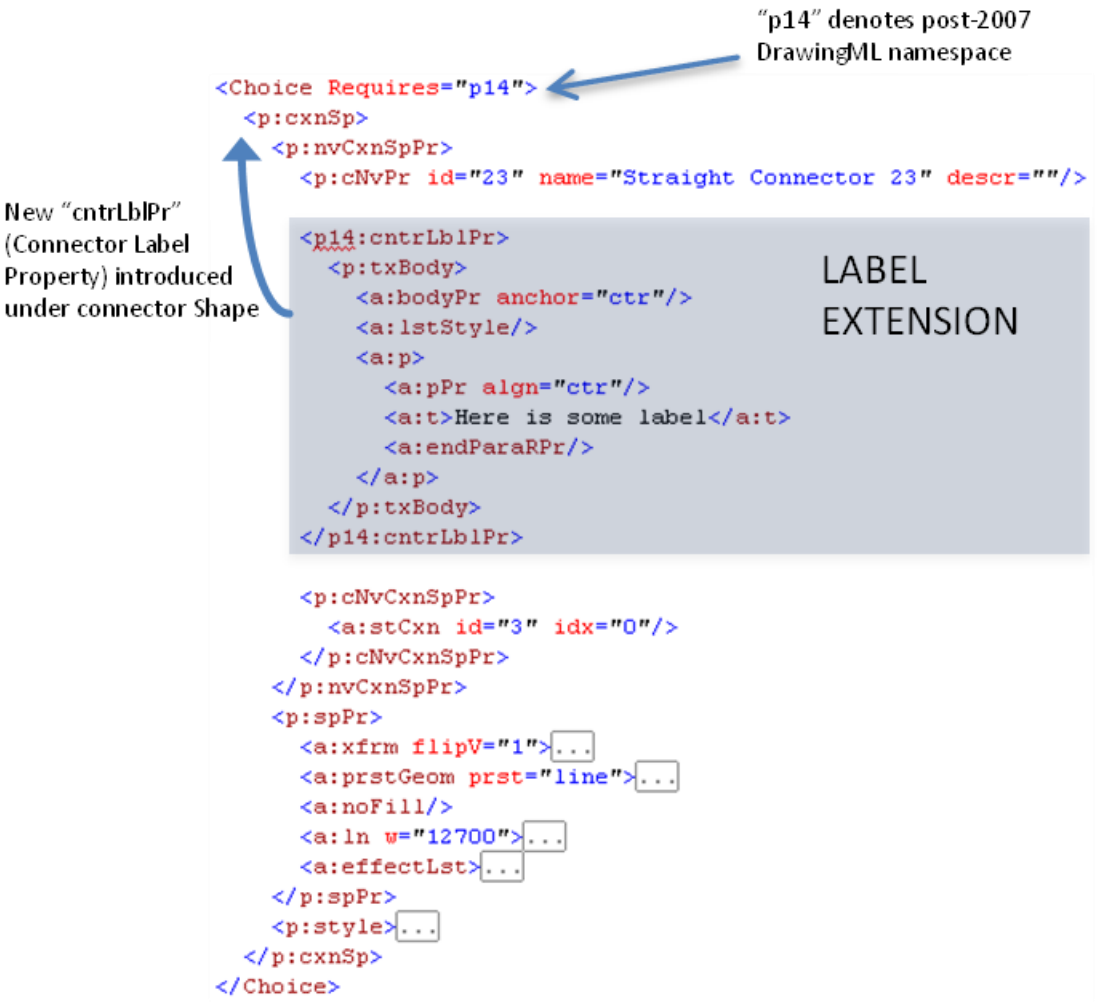
Two alternate representations are required: PML 2009's schema has been extended to natively understand how to represent a label on a connector; however, PML 2007 does not. With PML 2007, we approximate this feature by representing the connector and label independently. The label is represented using a textbox. To keep the two elements together, for convenience sake, they are grouped.

Looking at the corresponding XML, PML 2007's markup looks as follows:



```
<Choice Requires="p">
  <p:nvGrpSpPr>...
  <p:grpSpPr>...
  <p:grpSp>
    <p:nvGrpSpPr>...
    <p:grpSpPr>
      <a:xfrm>...
    </p:grpSpPr>
    <p:cxnSp>
      <p:nvCxnSpPr>
        <p:cNvPr id="31" name="Straight Connector 31" descr=""/>
        <p:cNvCxnSpPr/>
        <p:nvPr/>
      </p:nvCxnSpPr>
      <p:spPr>...
      <p:style>...
    </p:cxnSp>
    <p:sp>
      <p:nvSpPr>...
      <p:spPr>
        <a:xfrm>...
        <a:prstGeom prst="rect">...
        <a:noFill/>
      </p:spPr>
      <p:txBody>
        <a:bodyPr wrap="none">...
        <a:lstStyle/>
        <a:p>
          <a:r>
            <a:rPr lang="en-US" dirty="0" smtClean="0"/>
            <a:t>Here is some label</a:t>
          </a:r>
          <a:endParaRPr smtClean="0"/>
        </a:p>
      </p:txBody>
    </p:sp>
  </p:grpSp>
</Choice>
```

PML 2009 has been extended such that we may represent a label natively:



The final markup putting these choices together is as follows:

```
<p:sld xmlns:a="http://schemas.openxmlformats.org/drawingml/2006/3/main"
       xmlns:r="http://schemas.openxmlformats.org/officeDocument/2006/relationships"
       xmlns:p="http://schemas.openxmlformats.org/presentationml/2006/3/main"
       xmlns:p14="http://schemas.openxmlformats.org/presentationml/2008/3/main">
  <p:cSld name="">
    <p:spTree>
      <p:nvGrpSpPr>...
      <p:grpSpPr>...
      <AlternateContent>
        <Choice Requires="p14">
          <!-- Uplevel Choice goes here -->
        </Choice>
        <Choice Requires="p">
          <!-- Downlevel Choice goes here -->
        </Choice>
      </AlternateContent>
    </p:spTree>
  </p:cSld>
  <p:clrMapOvr>...
  <p:timing>...
</p:sld>
```

AlternateContent Block

8.3.4.2.3 AlternateContent Round-Trip Behavior

AlternateContent maintains multiple representations for the same content. Consider an extreme case. Using the example above, let's suppose one edited the label using PML 2007. As PML 2007 wouldn't understand future representations, there is no possibility that it could keep PML 2009's markup consistent with the edit performed. Considering a simple case, let's suppose one deleted the label in its entirety. PML 2007 would only know how to delete the corresponding textbox, and would not know how to update the corresponding cntrLblPr.

If this textbox contained sensitive information, one might consider this a security leak. The user's belief is that the information in the textbox was deleted, yet it persists in an alternate representation.

To solve this problem, all AlternateContent choices are discarded when an edit is performed at the location the AlternateContent is placed. It is the consuming client's responsibility to replace the discarded AlternateContent with a new representation.

If an edit to the label occurred in PML 2007, the PML 2009 version is discarded.

If an edit occurs in PML 2009, since PML 2009 understands both PML 2007 and PML 2009 schemas, it is possible for PML 2009 to write an updated AlternateContent Block encompassing an update to both choices.

End of informative text.

Office Open XML

Part 4: Markup Language Reference

December 2006

Table of Contents

Foreword

This multi-part Standard deals with Office Open XML Format-related technology, and consists of the following parts:

- Part 1: "Fundamentals"
- Part 2: "Open Packaging Conventions"
- Part 3: "Primer"
- **Part 4: "Markup Language Reference" (this document)**
- Part 5: "Markup Compatibility and Extensibility"

This part, Part 4, includes a number of annexes that refer to data files provided in electronic form only.

Introduction

This Part is one piece of a Standard that describes a family of XML schemas, collectively called *Office Open XML*, which define the XML vocabularies for word-processing, spreadsheet, and presentation documents, as well as the packaging of documents that conform to these schemas.

The goal is to enable the implementation of the Office Open XML formats by the widest set of tools and platforms, fostering interoperability across office productivity applications and line-of-business systems, as well as to support and strengthen document archival and preservation, all in a way that is fully compatible with the large existing investments in Microsoft Office documents.

1. Part Overview

This clause is informative.

For convenience, the following subclauses specify the root elements for each part. Full discussion of the use of each part can be found in Part 1 of this Office Open XML Standard.

1.1 WordprocessingML Part Summary

Part	Root Element	Ref.
Alternative Format Import	Not applicable	n/a
Comments	comments	§2.13.4.6
Document Settings	settings	§2.15.1.78
Endnotes	endnotes	§2.11.8
Font Table	fonts	§2.8.2.11
Footer	ftr	§2.10.3
Footnotes	footnotes	§2.11.15

End of informative text.

2. WordprocessingML Reference Material

The subordinate subclauses specify the semantics for the XML markup comprising a WordprocessingML document, as defined by Part 1 of this Standard.

2.1 Table of Contents

This subclause is informative.

End of informative text.

2.2 Main Document Story

A WordprocessingML document consists of a compilation of two types of information:

- Properties [*Example*: styles, numbering definitions, etc. *end example*]
- Stories [*Example*: main document, comments, headers, etc. *end example*]

In WordprocessingML, *stories* are defined as each unique region of content within a document into which the user can type. The most important story in a WordprocessingML document is the main document story, which contains the primary contents of the document. The main document story in WordprocessingML is stored inside the body element.

[*Example*: Consider a document with a single paragraph in the main document story. This document would require the following WordprocessingML in its main document part:

```
<w:document>
  <w:body>
    <w:p/>
  </w:body>
</w:document>
```

The fact that the paragraph is inside the body element makes it part of the main document story. *end example*]

2.2.1 background (Document Background)

This element specifies the background information for this document. This background shall be displayed on all pages of the document, behind all other document content.

The child elements of the background element are in the Vector Markup Language (VML) namespace, which allows any valid VML effect to be applied to the document's background.

For solid color fill backgrounds, however, the attributes on this element allow for the specification of use of any valid RGB or theme color value (the latter a reference to the document's themes part).

[*Example*: Consider a document which utilizes a gradient fill background moving between black and the accent5 theme color, as follows:

This background would require the following WordprocessingML markup:

```
<w:background w:color="9BBB59" w:themeColor="accent3">
  <v:background id="_x0000_s1025" o:bwmode="white" fillcolor="#9bbb59 [3206]"
o:targetscreensize="800,600">
    <v:fill color2="fill darken(118)" method="linear sigma" focus="100%"
type="gradientRadial">
      <o:fill v:ext="view" type="gradientCenter" />
    </v:fill>
  </v:background>
</w:background>
```

The resulting background consists of a single color fill of the `accent3` theme color from the themeColor attribute, layered under a `gradientCenter` fill from the fill attribute. *end example*]

Parent Elements
document (§2.2.3); glossaryDocument (§2.12.10)

Child Elements	Subclause
Any element from the urn:schemas-microsoft-com:vml namespace	§6.1
Any element from the urn:schemas-microsoft-com:office:office namespace	§6.2

Attributes	Description
color (Background Color)	Specifies the color for the background of the document. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the background color as appropriate. If the background specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. [*Example*: Consider a border color with value 2C34FF, as follows: `<w:background … w:color="2C34FF"/>` The background color shall therefore be the color with an RGB value of 44,52,255 (the decimal decoding of the hex value above). *end example*] The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
themeColor (Background Theme Color)	Specifies a theme color to be applied to the current background. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part, which allows color information to be set centrally in the document. If the color attribute is specified, its value shall be ignored in favor of the color resulting from the use of this attribute with any appropriate themeTint and themeShade attribute value calculations applied. [*Example*: Consider a background configured to use the accent5 theme color, resulting in the following WordprocessingML markup: `<w:background w:color="FFA8A0" w:themeColor="accent5" />` The background has a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, the RGB color value is ignored in favor of the accent5 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade	Specifies the shade value applied to the supplied theme color (if any) for this background.

Attributes	Description
(Border Theme Color Shade)	If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 60% applied to a background in a document. This shade is calculated as follows: $$S_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeShade value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}^{'} = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L^{'} = 0.53 * 0.75 = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:background w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this background. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to the document's background. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeTint value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:background w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>`

Attributes	Description
	end example] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Background">
   <complexContent>
      <extension base="CT_PictureBase">
         <attribute name="color" type="ST_HexColor" use="optional"/>
         <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
         <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
         <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.2.2 body (Document Body)

This element specifies the contents of the body of the document - the main document editing surface.

The document body contains what is referred to as *block-level markup* - markup which can exist as a sibling element to paragraphs in a WordprocessingML document.

[*Example*: Consider a document with a single paragraph in the main document story. This document would require the following WordprocessingML in its main document part:

```
<w:document>
  <w:body>
    <w:p/>
  </w:body>
</w:document>
```

The fact that the paragraph is inside the body element makes it part of the main document story. *end example*]

Parent Elements
document (§2.2.3)

Child Elements	Subclause
altChunk (Anchor for Imported External Content)	§2.17.3.1

permStart (Range Permission Start)	§2.13.7.2
proofErr (Proofing Error Anchor)	§2.13.8.1
sdt (Block-Level Structured Document Tag)	§2.5.2.30
sectPr (Document Final Section Properties)	§2.6.18
tbl (Table)	§2.4.36

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Body">
   <sequence>
      <group ref="EG_BlockLevelElts" minOccurs="0" maxOccurs="unbounded"/>
      <element name="sectPr" minOccurs="0" maxOccurs="1" type="CT_SectPr"/>
   </sequence>
</complexType>
```

2.2.3 document (Document)

This element specifies the contents of a main document part in a WordprocessingML document.

[*Example*: Consider the basic structure of the main document part in a basic WordprocessingML document, as follows:

```
<w:document>
  <w:body>
    <w:p/>
  </w:body>
</w:document>
```

All of the contents of the main document part are contained beneath the document element. *end example*]

Parent Elements
Root element of WordprocessingML Main Document part

Child Elements	Subclause
background (Document Background)	§2.2.1
body (Document Body)	§2.2.2

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Document">
   <complexContent>
      <extension base="CT_DocumentBase">
         <sequence>
            <element name="body" type="CT_Body" minOccurs="0" maxOccurs="1"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.3 Paragraphs and Rich Formatting

The basis of a WordprocessingML document is its actual text contents. Those text contents can be stored in many contexts (tables, text boxes, etc.), but the most basic form of text contents in WordprocessingML is the paragraph, specified using the p element (§2.3.1.22).

Within the paragraph, all rich formatting at the paragraph level is stored within the pPr element (§2.3.1.25; §2.3.1.26). [*Note*: Some examples of paragraph properties are alignment, border, hyphenation override, indentation, line spacing, shading, text direction, and widow/orphan control. *end note*]

Within the paragraph, text is grouped into one or more runs, represented by the r element (§2.3.2.23), which define a region of text with a common set of properties.

Just as a paragraph can have rich formatting, so too can a run. All of the elements inside an r element have their properties controlled by a corresponding optional rPr run properties element (§2.7.8.1; §2.3.2.26). [*Note*: Some examples of run properties are bold, underlined, or visible. *end note*]

Within runs, run content is the set of possible objects and characters which can be displayed in the document.

2.3.1 Paragraphs

The most basic unit of block-level content within a WordprocessingML document, *paragraphs* are stored using the p element (§2.3.1.22). A paragraph defines a distinct division of content with a WordprocessingML document which begins on a new line.

[*Example*: Consider the paragraph fragment "*The quick brown fox jumped … "* which is centered on a paragraph. The justification property is a paragraph level property, and therefore is expressed on the paragraph properties as follows:

```
<w:p>
  <w:pPr>
    <w:jc w:val="center"/>
    <w:rPr>
      <w:i/>
    </w:rPr>
  </w:pPr>
  <w:r>
    <w:rPr>
      <w:i/>
    </w:rPr>
    <w:t xml:space="preserve">The quick brown fox jumped … </w:t>
  </w:r>
</w:p>
```

Notice that each run specifies the character formatting information for its contents, and the paragraph specifies the paragraph level formatting (the center-justification). It is also notable that since leading and trailing whitespace is not normally significant in XML; some runs require a designating specifying that their whitespace is significant via the xml:space element. *end example*]

A paragraph's properties are specified via the pPr element (§2.3.1.25; §2.3.1.26). [*Note*: Some examples of paragraph properties are alignment, border, hyphenation override, indentation, line spacing, shading, text direction, and widow/orphan control. *end note*]

2.3.1.1 adjustRightInd (Automatically Adjust Right Indent When Using Document Grid)

This element specifies whether the right indent shall be automatically adjusted for the given paragraph when a document grid has been defined for the current section using the docGrid element (§2.6.5), modifying of the current right indent used on this paragraph.

[*Note*: This setting is used in order to ensure that the line breaking for that paragraph is not determined by the width of the final character on the line. *end note*]

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, its value is assumed to be `true`.

[*Example*: Consider a paragraph in which the right indent on the current paragraph should not be automatically determined based on the character pitch set in the document grid. This setting would be specified using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    …
    <w:adjustRightInd w:val="false" />
  </w:pPr>
  …
</w:p>
```

By explicitly setting the val to `false`, this paragraph will use its specified right indent settings regardless of the presence of the document grid for the parent section. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.2 autoSpaceDE (Automatically Adjust Spacing of Latin and East Asian Text)

This element specifies whether inter-character spacing shall automatically be adjusted between regions of Latin text and regions of East Asian text in the current paragraph. These regions shall be determined by the Unicode character values of the text content within the paragraph.

[*Note*: This property is used to ensure that the spacing between regions of Latin text and adjoining East Asian text is sufficient on each side such that the Latin text can be easily read within the East Asian text. *end note*]

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, its value is assumed to be `true`.

[*Example*: Consider a paragraph in which the spacing should not be automatically adjusted based on the presence of Latin and East Asian text. This setting would be specified using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    …
    <w:autoSpaceDE w:val="false" />
  </w:pPr>
  …
</w:p>
```

By explicitly setting the val to `false`, this paragraph shall not automatically adjust the spacing of adjoining Latin and East Asian text. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property:

Attributes	Description
	<w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.3 autoSpaceDN (Automatically Adjust Spacing of East Asian Text and Numbers)

This element specifies whether inter-character spacing shall automatically be adjusted between regions of numbers and regions of East Asian text in the current paragraph. These regions shall be determined by the Unicode character values of the text content within the paragraph.

[*Note*: This property is used to ensure that the spacing between regions of numbers and adjoining East Asian text is sufficient on each side such that the numbers can be easily read within the East Asian text. *end note*]

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, its value is assumed to be true.

[*Example*: Consider a paragraph in which the spacing should not be automatically adjusted based on the presence of numbers and East Asian text. This setting would be specified using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    …
    <w:autoSpaceDN w:val="false" />
  </w:pPr>
  …
</w:p>
```

By explicitly setting the val to false, this paragraph will not automatically adjust the spacing of adjoining numbers and East Asian text. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.4 bar (Paragraph Border Between Facing Pages)

This element specifies the border which may be displayed on the inside edge of the paragraph when the parent's section settings specify that the section shall be printed using mirrored margins using the mirrorMargins element (§2.15.1.57). [*Note*: This information is present in the WordprocessingML for the purposes of legacy document format compatibility, and it may be removed and/or ignored as required. *end note*]

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no bar border shall be applied to the current paragraph.

[*Example*: Consider the following paragraph's WordprocessingML definition for its paragraph borders:

```
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
        w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
        w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
        w:themeColor="accent2" w:themeTint="33" />
```

```
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
        w:themeColor="accent3" w:themeTint="99" />
      <w:bar w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
        w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>Sample paragraph.</w:t>
  </w:r>
</w:p>
```

This paragraph has a single line bar border as defined by the bar element. *end example*]

Parent Elements
pBdr (§2.3.1.24)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML:

Attributes	Description
	<w:bottom w:frame="true" ... /> This frame's val is true, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: <w:bottom w:shadow="true" ... /> This frame's val is true, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of text in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points. [*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows: <w:pgBorders w:offsetFrom="page"> <w:bottom … w:space="24/> </w:pgBorders The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />

Attributes	Description
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634.

Attributes	Description
	This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) = 0.71$$

Attributes	Description
	Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.3.1.5 between (Paragraph Border Between Identical Paragraphs)

This element specifies the border which shall be displayed between each paragraph in a set of paragraphs which have the same set of paragraph border settings.

To determine if any two adjoining paragraphs should have a between border or an individual top and bottom border, the set of borders on the two adjoining paragraphs are compared. If the border information on those two paragraphs is identical for all possible paragraphs borders, then the between border is displayed. Otherwise, each paragraph shall use its bottom and top border, respectively. If this border specifies a space attribute, that value is ignored - this border is always located at the bottom of each paragraph with an identical following paragraph, taking into account any space after the line pitch.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no between border shall be applied between identical paragraphs.

[*Example*: Consider the following two paragraphs' WordprocessingML definition:

```
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>First paragraph.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="0" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
```

```
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>Second paragraph.</w:t>
  </w:r>
</w:p>
```

Since the bottom paragraph border is different between the two paragraphs (the bottom space value goes from 1 to 0), these paragraphs do not use the between border, and instead paragraph one uses its bottom border, and paragraph two uses its top border. If those values were identical, then paragraph one would have a between brder below it, and paragraph two would have no top border. *end example*]

Parent Elements

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is

Attributes	Description
	specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the

Attributes	Description
	page offset shall be 24 points. *end example*] The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />

Attributes	Description
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634.

Attributes	Description
	This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$

Attributes	Description
	$= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.3.1.6 bidi (Right to Left Paragraph Layout)

This element specifies that this paragraph shall be presented using a right to left direction. This property only affects the set of paragraph-level properties, and shall not affect the layout of text within the contents of this paragraph.

[*Example*: Consider a paragraph with the bidi property set as follows:

```
<w:p>
    <w:pPr>
      <w:bidi/>
    </w:pPr>
    ...
</w:p>
```

This paragraph direction is now right to left, which means that all paragraph properties are displayed right to left (e.g. the paragraph marker glyph (if any) is displayed on the right, and indentation for the first line of the paragraph occurs on the right side of the page). *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.7 bottom (Paragraph Border Between Identical Paragraphs)

This element specifies the border which shall be displayed below a set of paragraphs which have the same set of paragraph border settings.

To determine if any two adjoining paragraphs shall have an individual top and bottom border or a between border, the set of borders on the two adjoining paragraphs are compared. If the border information on those

two paragraphs is identical for all possible paragraphs borders, then the between border is displayed. Otherwise, the final paragraph shall use its bottom border and the following paragraph shall use its top border, respectively. If this border specifies a space attribute, that value determines the space after the bottom of the text (ignoring any space below) which should be left before this border is drawn, specified in points.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no between border shall be applied below identical paragraphs.

[*Example*: Consider the following two paragraphs' WordprocessingML definition:

```
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>First paragraph.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="0" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
```

```
    </w:pPr>
    <w:r>
      <w:t>Second paragraph.</w:t>
    </w:r>
  </w:p>
```

Since the paragraph border is different between the two paragraphs (the bottom space value goes from 1 to 0), paragraph one uses its bottom border, which is located one point below the text in that paragraph. *end example*]

Parent Elements
pBdr (§2.3.1.24)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is true, indicating that the border frame effect shall be applied. *end*

Attributes	Description
	example] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.

Attributes	Description

	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75 = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$ and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2"`

Attributes	Description
	w:themeShade="BF"/>

end example]

The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106). |
| themeTint (Border Theme Color Tint) | Specifies the tint value applied to the supplied theme color (if any) for this border instance.

If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border.

The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border.

[*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows:

$$T_{xml} = 0.6 * 255$$
$$= 153$$
$$= 99(hex)$$

The resulting themeTint value in the file format would be 99. *end example*]

Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows:

- Convert the color to the HSL color format (values from 0 to 1)
- Modify the luminance factor as follows:

$$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$

- Convert the resultant HSL color to RGB

[*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD.

The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$.

Applying the tint formula with a tint percentage of 60% to the luminance, we get:

$$L' = 0.53 * 0.6 + (1 - .6)$$
$$= 0.71$$

Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. |

Attributes	Description
	This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.3.1.8 cnfStyle (Paragraph Conditional Formatting)

This element specifies the set of conditional table style formatting properties which have been applied to this paragraph, if this paragraph is contained within a table cell. [*Note*: This property is an optimization which may be used by consumers to determine if a given property on a paragraph is the result of the table style properties vs. direct formatting on the paragraph itself. *end note*]

If this property is specified on a paragraph which is not contained within a table cell, then its contents shall be ignored when reading the contents of the document.

[*Example*: Consider a paragraph in the top right corner of a table with a table style applied. This paragraph would need to specify the following WordprocessingML:

```
<w:p>
  <w:pPr>
    <w:cnfStyle w:val="101000000100" />
    ...
  <//w:pPr>
  ...
</w:p>
```

This paragraph specifies that it has the conditional properties from the table style for the first column, first row, and the NW corner of the parent table by setting the appropriate bits in the val attribute. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (Conditional Formatting Bit Mask)	Specifies the set of conditional formatting properties that have been applied to this object. These properties are expressed using a string serialization of a binary bitmask for each of the following properties (reading from the first character position right): • First Row - Is this the first row of the table? • Last Row - Is this the last row of the table? • First Column - Does this belong to the first column of the table? • Last Column - Does this belong to the last column of the table? • Band 1 Vertical - Does this belong to a column which should receive band 1 formatting? This property specifies whether the cell should receive the formatting specified for odd-numbered columns (e.g. 1,3,5,...) • Band 2 Vertical - Does this belong to a column which should receive band 2 formatting? This property specifies whether the cell should receive the formatting specified for even-numbered columns (e.g. 2,4,6...) • Band 1 Horizontal - Does this receive band 1 formatting? This property specifies whether the cell should receive the formatting specified for odd-numbered rows (e.g. 1,3,5,...) • Band 2 Horizontal - Does this receive band 2 formatting? This property specifies whether the cell should receive the formatting specified for even-numbered rows (e.g. 2,4,6...) • NE Cell - Is this part of the top-right corner of the table? • NW Cell - Is this part of the top-left corner of the table? • SE Cell - Is this part of the bottom-right corner of the table? • SW Cell - Is this part of the bottom-left corner of the table?

Attributes	Description

	For each of these properties, a value of 1 in the specified character position in the string means that the value is true, a value of 0 means false. All values must be specified.
	
	[*Example*: Consider a paragraph in the top right corner of a table with a table style applied. This paragraph would need to specify the following WordprocessingML:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:cnfStyle w:val="101000000100" />`
	`  ...`
	`  </w:pPr>`
	`  ...`
	`</w:p>`
	
	This paragraph specifies that it has the conditional properties from the table style for the first column, first row, and the NW corner of the parent table by setting the appropriate bits in the val attribute. *end example*]
	
	The possible values for this attribute are defined by the ST_Cnf simple type (§2.18.11).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Cnf">
    <attribute name="val" type="ST_Cnf" use="required"/>
</complexType>
```

2.3.1.9 contextualSpacing (Ignore Spacing Above and Below When Using Identical Styles)

This element specifies that any space specified before or after this paragraph, specified using the spacing element (§2.3.1.33), should not be applied when the preceding and following paragraphs are of the same paragraph style, affecting the top and bottom spacing respectively. [*Example*: This value is typically used for paragraphs in lists, in which any space between subsequent list items, even if inherited from another style, is not desirable. *end example*]

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then spacing is not ignored. If it is present, then the spacing above or below on this paragraph is subtracted from the spacing which would have been present if contextual spacing was off, never going below zero.

[*Example*: Consider two paragraphs defined as follows:

```
<w:p>
  <w:pPr>
    <w:pStyle w:val="TestParagraphStyle" />
    <w:spacing w:after="200"/>
```

```
      <w:contextualSpacing/>
    </w:pPr>
    …
  </w:p>
  <w:p>
    <w:pPr>
      <w:pStyle w:val="TestParagraphStyle" />
      <w:spacing w:before="240"/>
    </w:pPr>
    …
  </w:p>
```

The first paragraph specifies a spacing after of 10 points, and the second paragraph specifies a spacing before of 12 points, therefore according to the rules on the spacing element, the net paragraph spacing should be 12 points. However, since the first paragraph specifies that its spacing should be omitted between paragraphs of the same style, and the two paragraphs use the same TestParagraphStyle, that value is subtracted from the total, therefore the paragraphs are spaced by 2 points. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.10 divId (Associated HTML div ID)

This element specifies that this paragraph should be located within the specified HTML `div` tag when this document is saved in HTML format. This ID is then used to look up the associated div stored in the divs (§2.15.2.8) element. [*Note*: This element is used to preserve the fidelity of existing HTML documents when saved in the WordprocessingML format. *end note*].

If the paragraph does not specify this element, then any `div` referenced by the previous paragraph is closed, and this paragraph shall not belong to any `div` when saved as HTML. If this specified id does not exist in the collection of `div`s the current document, then any `div` referenced by the previous paragraph is closed, and this paragraph shall not belong to any `div` when saved as HTML.

[*Example*: Consider the following WordprocessingML paragraph fragment:

```
<w:p>
  <w:pPr>
    <w:divId w:val="1512645511" />
  </w:pPr>
</w:p>
```

This paragraph specifies that it belongs to the HTML `div` with id `1512645511`, stored in the divs element. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.3.1.11 framePr (Text Frame Properties)

This element specifies information about the current paragraph with regard to *text frames*. *Text frames* are paragraphs of text in a document which are positioned in a separate region or frame in the document, and can be positioned with a specific size and position relative to non-frame paragraphs in the current document.

The first piece of information specified by the framePr element is that the current paragraph is actually part of a text frame in the document. This information is specified simply by the presence of the framePr element in paragraph's properties. If the framePr element is omitted, the paragraph shall not be part of any text frame in the document.

The second piece of information concerns the set of paragraphs which are part of the current text frame in the document. This is determined based on the attributes on the framePr element. If the set of attribute values specified on two adjacent paragraphs is identical, then those two paragraphs shall be considered to be part of the same text frame and rendered within the same frame in the document.

[*Example*: Consider a document in which the following two paragraphs are located adjacent to one another:

```
<w:p>
  <w:pPr>
    <w:framePr w:w="2191" w:h="811" w:hRule="exact" w:hSpace="180"
w:wrap="around" w:vAnchor="text" w:hAnchor="page" w:x="1921"/>
  </w:pPr>
  <w:r>
    <w:t>Paragraph One</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:framePr w:w="2191" w:h="810" w:hRule="exact" w:hSpace="180"
w:wrap="around" w:vAnchor="text" w:hAnchor="page" w:x="1921"/>
  </w:pPr>
  <w:r>
    <w:t>Paragraph Two.</w:t>
  </w:r>
</w:p>
```

These two paragraphs, although each is a part of a text frame due to the presence of the framePr element, are different text frames because of the differing h value - 810 vs. 811. *end example*]

The positioning of the frame relative to the properties stored on its attribute values shall be calculated relative to the next paragraphs in the document which is itself not part of a text frame.

[*Example*: Consider a document in which the following three paragraphs are located adjacent to one another:

```
<w:p>
  <w:pPr>
    <w:framePr w:w="2191" w:h="811" w:hRule="exact" w:hSpace="180"
w:wrap="around" w:vAnchor="text" w:hAnchor="page" w:x="1921"/>
  </w:pPr>
  <w:r>
    <w:t>Paragraph One</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:framePr w:w="2191" w:h="811" w:hRule="exact" w:hSpace="180"
w:wrap="around" w:vAnchor="text" w:hAnchor="page" w:x="1921"/>
  </w:pPr>
  <w:r>
    <w:t>Paragraph Two.</w:t>
  </w:r>
</w:p>
<w:p/>
```

The first two paragraphs form a single text frame, which is anchored using its attribute values relative to the first non-frame paragraph following it (the third paragraph in the example). *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
anchorLock (Lock Frame Anchor to Paragraph)	Specifies that the frame shall always remain in the same logical position relative to the non-frame paragraphs which precede and follow it in this document. This means that consumers which modify this document shall ensure that this text frame remains directly above the non-frame paragraph which it is currently above, by adjusting the frame's positioning properties as needed as the paragraph is moved throughout the document rather than moving the frame's logical location within the paragraphs in the document, if that would be more appropriate. If this attribute is omitted, then this frame shall not have a locked anchor position. [*Example*: Consider the following WordprocessingML paragraph contained in a text

Attributes	Description

	frame:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:w="2419" w:h="2189" w:hRule="exact"`
	`w:hSpace="187" w:wrap="around" w:vAnchor="text"`
	`w:hAnchor="page" w:x="1643" w:y="73" w:anchorLock="1"/>`
	`  </w:pPr>`
	`  <w:r>`
	`  <w:t>Text Frame Content.</w:t>`
	`  </w:r>`
	`</w:p>`
	
	This text frame has a locked anchor using the anchorLock attribute. If the text frame is moved down in the document, the text frame properties must be adjusted to be relative to the parent paragraph's same logical position - the paragraph cannot be relocated in the document, which results in changes to the frame's properties as follows:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:w="2419" w:h="2189" w:hRule="exact"`
	`w:hSpace="187" w:wrap="around" w:vAnchor="text"`
	`w:hAnchor="page" w:x="1643" w:y="-5247" w:anchorLock="1"/>`
	`  </w:pPr>`
	`  <w:r>`
	`  <w:t>Text Frame Content.</w:t>`
	`  </w:r>`
	`</w:p>`
	
	The non-frame paragraph was relocated 5320 twentieths of a point below its original location in the document, and the frame's vertical positioning properties were adjusted to ensure its logical location within the paragraph ordering was constant while its visual location was changed. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

dropCap (Drop Cap Frame)	Specifies that the current frame contains a drop cap to be located at the beginning of the next non-frame paragraph in the document. Its contents shall be used to specify how that drop cap should be positioned relative to that paragraph. If this attribute is omitted, then this frame shall not be considered a drop cap frame. [*Note*: Although a drop cap is simply a text frame, this element is used to determine how the cap should be positioned relative to the following non-frame paragraph in relative terms (see possible values), rather than relying on absolute sizing. *end note*] [*Example*: Consider the following paragraph containing a text frame which should be

Attributes	Description

	positioned as a drop cap:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:dropCap="margin" w:lines="3" w:hSpace="432" w:wrap="around" w:vAnchor="text" w:hAnchor="page" />`
	`  </w:pPr>`
	`  <w:r>`
	`  <w:t>A</w:t>`
	`  </w:r>`
	`</w:p>`
	
	The dropCap attribute specifies a value of `margin`, so this drop cap will be placed outside of the text margin before the start of the current text. *end example*]
	
	The possible values for this attribute are defined by the ST_DropCap simple type (§2.18.24).

h (Frame Height)	Specifies the frame's height.
	
	This height is expressed in twentieths of a point.
	
	If this attribute is omitted, then its value shall be assumed to be `0`.
	
	The meaning of the value of the h attribute is defined based on the value of the hRule attribute for this text frame as follows:
	• If the value of hRule is `auto`, then the frame's height should be automatically determined based on the height of its contents. This value is ignored.
	• If the value of hRule is `atLeast`, then the frame's height should be at least the value of this attribute.
	• If the value of hRule is `exact`, then the frame's height should be exactly the value of this attribute.
	
	[*Example*: Consider the following paragraph containing a text frame:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:w="2419" w:h="2189" w:hRule="atLeast" w:hspace="187" w:wrap="around" w:vanchor="text" w:hanchor="page" w:x="1643" w:y="73" />`
	`  </w:pPr>`
	`  <w:r>`
	`  <w:t>Text Frame Content.</w:t>`
	`  </w:r>`
	`</w:p>`
	
	The h attribute specifies a value of 2189 twentieths of a point, so this text frame will be a

Attributes	Description
	minimum of 2189 twentieths of a point high regardless of its contents, since its hRule value is set to atLeast. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

hAnchor (Frame Horizontal Positioning Base)	Specifies the base object from which the horizontal positioning in the x attribute should be calculated.
	
	A text frame may be horizontally positioned relative to:
	• The vertical edge of the page before any runs of text (the left edge for left-to-right paragraphs, the right edge for right-to-left paragraphs)
	• The vertical edge of the text margin before any runs of text (the left edge for left-to-right paragraphs, the right edge for right-to-left paragraphs)
	• The vertical edge of the text margin for the column in which the anchor paragraph is located
	
	If this attribute is omitted, then its value shall be assumed to be page.
	
	[*Example*: Consider a text frame which should be positioned one inch to the right of its column in a left-to-right document. This text frame would be specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:framePr … w:x="1440" w:hAnchor="column" />`
	`</w:pPr>`
	
	These frame properties specify that they are relative to the anchor paragraph's column, and that relative to that column, the frame should be 1440 twentieths of a point in the direction of the flow of text (right, in this case). *end example*]
	
	The possible values for this attribute are defined by the ST_HAnchor simple type (§2.18.40).

hRule (Frame Height Type)	Specifies the meaning of the height specified for this frame. The meaning of the value of the h attribute is defined based on the value of the hRule attribute for this text frame as follows: • If the value of hRule is auto, then the frame's height should be automatically determined based on the height of its contents. The h value is ignored. • If the value of hRule is atLeast, then the frame's height should be at least the value the h attribute. • If the value of hRule is exact, then the frame's height should be exactly the value of the h attribute. If this attribute is omitted, then its value shall be assumed to be auto.

Attributes	Description

	[*Example*: Consider the following paragraph containing a text frame:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:w="2419" w:h="2189" w:hRule="atLeast"`
	`w:hSpace="187" w:wrap="around" w:vAnchor="text"`
	`w:hAnchor="page" w:x="1643" w:y="73" />`
	`  </w:pPr>`
	`  <w:r>`
	`  <w:t>Text Frame Content.</w:t>`
	`  </w:r>`
	`</w:p>`
	
	The h attribute specifies a value of 2189 twentieths of a point, so this text frame will be a minimum of 2189 twentieths of a point high regardless of its contents, since its hRule value is set to atLeast. *end example*]
	
	The possible values for this attribute are defined by the ST_HeightRule simple type (§2.18.42).

hSpace (Horizontal Frame Padding)	Specifies the minimum distance which shall be maintained between the current text frame and any non-frame text which has been allowed to flow around this object when the wrap attribute on this text frame is set to around.
	
	This distance is expressed in twentieths of a point.
	
	If the wrap value is not set to around, this value shall be ignored. If this attribute is omitted, its value shall be assumed to be 0.
	
	[*Example*: Consider a text frame which should have a minimum of a one-half inch spacing from any non-frame text on its left and right sides. This constraint would be specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:framePr ...w:hSpace="720" w:wrap="around" />`
	`</w:pPr>`
	
	The wrap value of around allows text to wrap around this text frame, and the hSpace attribute specifies that the spacing between text and this frame shall be a minimum of 720 twentieths of a point. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

lines (Drop Cap Vertical Height in Lines)	Specifies the number of lines in the non-frame paragraph to which this text frame is anchored which should be used to calculate the drop cap's height. If the current frame is not a drop cap (the parent framePr element does not have the

Attributes	Description

	dropCap attribute), this value is ignored. If the current text frame is a dropped cap and this attribute is present, then any other vertical positioning information shall be ignored.
	
	If this attribute is omitted, then its value shall be considered to be 1.
	
	[*Example*: Consider the following paragraph containing a text frame which should be positioned as a drop cap:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:dropCap="margin" w:lines="3" w:hSpace="432" w:wrap="around" w:vAnchor="text" w:hAnchor="page" W:y="400" w:yAlign="text" />`
	`  </w:pPr>`
	`  <w:r>`
	`  <w:t>O</w:t>`
	`  </w:r>`
	`</w:p>`
	
	Since this frame is being used as a dropped cap, the y and yAlign attributes are ignored and the height of the drop cap is the first three lines of the anchor paragraph. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

vAnchor (Frame Vertical Positioning Base)	Specifies the base object from which the horizontal positioning in the y attribute should be calculated.
	
	A text frame may be horizontally positioned relative to:
	• The horizontal edge of the page before any runs of text (the top edge for top-to-bottom sections, the bottom for bottom-to-top sections)
	• The horizontal edge of the text margin before any runs of text (the top edge for top-to-bottom sections, the bottom for bottom-to-top sections)
	• The horizontal edge of the page before any runs of text (the top edge for top-to-bottom sections, the bottom for bottom-to-top sections)
	
	If this attribute is omitted, then its value shall be assumed to be page.
	
	[*Example*: Consider a text frame which should be positioned two inches below the page top in a top-to-bottom document. This text frame would be specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:framePr … w:y="2880" w:vAnchor="page" />`
	`</w:pPr>`

Attributes	Description
	These frame properties specify that they are relative to the anchor page, and that relative to that column, the frame should be 2880 twentieths of a point in the direction of the flow of text (down, in this case). *end example*] The possible values for this attribute are defined by the ST_VAnchor simple type (§2.18.109).

vSpace (Vertical Frame Padding)	Specifies the minimum distance which shall be maintained between the current text frame and any non-frame text which is above or below this text frame.
	
	This distance is expressed in twentieths of a point.
	
	If this attribute is omitted, its value shall be assumed to be 0.
	
	[*Example*: Consider a text frame which should have a minimum of a one-half inch spacing from any non-frame text on its top and bottom sides. This constraint would be specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:framePr … w:vSpace="720" />`
	`</w:pPr>`
	
	The vspace attribute specifies that the spacing between text and this frame shall be a minimum of 720 twentieths of a point. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

w (Frame Width)	Specifies the exact value for this text frame's width.
	
	This value is specified in twentieths of a point.
	
	When this attribute is present, the text frame shall be rendered to the exact width specified. If this attribute is omitted, the text frame width shall be automatically determined by the maximum line width of the content within the text frame.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a text frame:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:w="2419" w:h="2189" w:hRule="atLeast"`
	`w:hspace="187" w:wrap="around" w:vanchor="text"`
	`w:hanchor="page" w:x="1643" w:y="73" />`
	`  </w:pPr>`
	`  <w:r>`
	`  <w:t>Text Frame Content.</w:t>`
	`  </w:r>`
	`</w:p>`

Attributes	Description
	This text frame specifies that its width shall be exactly 2419 twips. If this attribute was removed, the text frame would be rendered at the width of the content `Text Frame Content`. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

wrap (Text Wrapping Around Frame)	Specifies the type of text wrapping which should be allowed around the contents of this text frame. This attribute determines if non-frame text shall be allowed to flow around the contents of this frame.
	
	If this attribute is omitted, its value shall be assumed to be `around`.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a text frame:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:w="2419" w:h="2189" w:hRule="atLeast" w:hSpace="187" w:wrap="around" w:vAnchor="text" w:hAnchor="page" w:x="1643" w:y="73" />`
	`  </w:pPr>`
	`  <w:r>`
	`  <w:t>Text Frame Content.</w:t>`
	`  </w:r>`
	`</w:p>`
	
	This text frame specifies that when the frame is rendered on the page, any non-text frame paragraphs which would normally flow onto the same lines shall be allowed to do so. *end example*]
	
	The possible values for this attribute are defined by the ST_Wrap simple type (§2.18.113).

x (Absolute Horizontal Position)	Specifies an absolute horizontal position for the text frame. This absolute position is specified relative to the horizontal anchor specified by the hAnchor attribute for this text frame. This value is expressed in twentieths of a point. If it is positive, then the text frame is positioned after the anchor object in the direction of horizontal text flow in this document. If it is negative, then the text frame is positioned before the anchor object in the direction of horizontal text flow in this document. If the xAlign attribute is also specified, then this value is ignored. If this attribute is omitted, then its value shall be assumed to be `0`. [*Example*: Consider the following WordprocessingML fragment specifying a text frame:

Attributes	Description
	<w:p> <w:pPr> <w:framePr w:w="2419" w:h="2189" w:hRule="atLeast" w:hSpace="187" w:wrap="around" w:vAnchor="text" w:hAnchor="page" w:x="1643" w:y="73" /> </w:pPr> <w:r> <w:t>Text Frame Content.</w:t> </w:r> </w:p> This text frame specifies that it should be located exactly 1643 twentieths of a point after the vertical edge of the page (from the hAnchor attribute). *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).
xAlign (Relative Horizontal Position)	Specifies a relative horizontal position for the text frame. This relative position is specified relative to the horizontal anchor specified by the hAnchor attribute for this text frame. If omitted, this attribute is not specified and the value of the x attribute determines the absolute horizontal position of the text frame. If specified, the position for this attribute supersede any value which is specified in the x attribute, and that value is ignored. [*Example*: Consider the following WordprocessingML fragment specifying a text frame: <w:p> <w:pPr> <w:framePr w:w="2419" w:h="2189" w:hRule="atLeast" w:hSpace="187" w:wrap="around" w:vAnchor="text" w:hAnchor="page" w:x="1643" w:xAlign="left" w:y="73" /> </w:pPr> <w:r> <w:t>Text Frame Content.</w:t> </w:r> </w:p> This text frame specifies that it has a horizontal placement of exactly 1643 twentieths of a point relative to the page, but that exact placement is overridden by the presence of the xAlign attribute to place the frame on the left side of the page. *end example*] The possible values for this attribute are defined by the ST_XAlign simple type (§2.18.114).
y (Absolute Vertical Position)	Specifies an absolute vertical position for the text frame. This absolute position is specified relative to the vertical anchor specified by the vAnchor attribute for this text frame.

Attributes	Description

	This value is expressed in twentieths of a point. If it is positive, then the text frame is positioned after the anchor object in the direction of vertical text flow in this document. If it is negative, then the text frame is positioned before the anchor object in the direction of vertical text flow in this document.
	
	If the yAlign attribute is also specified, then this value is ignored. If this attribute is omitted, then its value shall be assumed to be 0.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a text frame:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:w="2419" w:h="2189" w:hRule="atLeast"`
	`w:hSpace="187" w:wrap="around" w:vAnchor="text"`
	`w:hAnchor="page" w:x="1643" w:y="73" />`
	`  </w:pPr>`
	`  <w:r>`
	`  <w:t>Text Frame Content.</w:t>`
	`  </w:r>`
	`</w:p>`
	
	This text frame specifies that it should be located exactly 79 twentieths of a point below the top vertical edge of the anchor's paragraph's text (from the vAnchor attribute), assuming that the vertical text direction is top to bottom. *end example*]
	
	The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

yAlign (Relative Vertical Position)	Specifies a relative vertical position for the text frame. This relative position is specified relative to the vertical anchor specified by the vAnchor attribute for this text frame.
	
	If omitted, this attribute is not specified and the value of the y attribute determines the absolute horizontal position of the text frame. If specified, the position for this attribute supersedes any value which is specified in the y attribute, and that value is ignored, unless the vAnchor is set to text, in which case any relative positioning is not allowed, and is itself ignored.
	
	[*Example*: Consider the following WordprocessingML fragment specifying a text frame:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:framePr w:w="2419" w:h="2189" w:hRule="atLeast"`
	`w:hSpace="187" w:wrap="around" w:vAnchor="margin"`
	`w:hAnchor="page" w:x="1643" w:y="73" w:yAlign="center" />`
	`  </w:pPr>`
	`  <w:r>`

Attributes	Description
	<w:t>Text Frame Content.</w:t> </w:r> </w:p> This text frame specifies that it has a vertical placement of exactly 73 twentieths of a point relative to the top margin, but that exact placement is overridden by the presence of the yAlign attribute to place the frame in the center of the margin. *end example*] The possible values for this attribute are defined by the ST_YAlign simple type (§2.18.115).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FramePr">
   <attribute name="dropCap" type="ST_DropCap" use="optional"/>
   <attribute name="lines" type="ST_DecimalNumber" use="optional"/>
   <attribute name="w" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="h" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="vSpace" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="hSpace" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="wrap" type="ST_Wrap" use="optional"/>
   <attribute name="hAnchor" type="ST_HAnchor" use="optional"/>
   <attribute name="vAnchor" type="ST_VAnchor" use="optional"/>
   <attribute name="x" type="ST_SignedTwipsMeasure" use="optional"/>
   <attribute name="xAlign" type="ST_XAlign" use="optional"/>
   <attribute name="y" type="ST_SignedTwipsMeasure" use="optional"/>
   <attribute name="yAlign" type="ST_YAlign" use="optional"/>
   <attribute name="hRule" type="ST_HeightRule" use="optional"/>
   <attribute name="anchorLock" type="ST_OnOff" use="optional"/>
</complexType>
```

2.3.1.12 ind (Paragraph Indentation)

This element specifies the set of indentation properties applied to the current paragraph.

Indentation settings are overriden on an individual basis - if any single attribute on this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If any single attribute on this element is never specified in the style hierarchy, then no indentation of that type is applied to the paragraph.

[*Example*: Consider a paragraph which should have a one inch indentation from the text margins on both the left and the right sides, except for the first line in each paragraph, which should only be indented one quarter of an inch from the text margin (on the side which begins the flow of text for this paragraph). This set of indentations is specified using the following WordprocessingML:

```
<w:pPr>
  <w:ind w:left="1440" w:right="1440" w:hanging="1080" />
</w:pPr>
```

This set of indentation properties specifies that a 1440 twentieths of a point indentation should be provided on both the left and the right side of the text margins for this paragraph, and that a 1080 twentieths of a point hanging indent (towards the text margin) should be applied to the text in the first paragraph, giving it a net one-quarter inch indent from the text margin. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description

firstLine (Additional First Line Indentation)	Specifies the additional indentation which shall be applied to the first line of the parent paragraph. This additional indentation is specified relative to the paragraph indentation which is specified for all other lines in the parent paragraph.
	
	The firstLine and hanging attributes are mutually exclusive, if both are specified, then the firstLine value is ignored. If the firstLineChars attribute is also specified, then this value is ignored. If this attribute is omitted, then its value shall be assumed to be zero (if needed).
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:ind w:left="1440" w:right="720" w:firstLine="1440" />`
	`</w:pPr>`
	
	This set of indentations specifies that the first line should be indented 1440 twentieths of a point (one inch) from the indentation specified for all remaining paragraphs, which is the 1440 twentieths of a point, as specified by the left attribute. This gives the first line a two inch indentation from the text margin. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

firstLineChars (Additional First Line Indentation in Character Units)	Specifies the additional indentation which shall be applied to the first line of the parent paragraph. This additional indentation is specified relative to the paragraph indentation which is specified for all other lines in the parent paragraph. It is specified in one hundredths of a character unit. The firstLineChars and hangingChars attributes are mutually exclusive, if both are specified, then the firstLineChars value is ignored. If the firstLine attribute is also specified, then this value supersedes its other value. If this attribute is omitted, then its value shall be assumed to be zero (if needed). [*Example*: Consider the following WordprocessingML fragment: `<w:pPr>`

Attributes	Description
	<w:ind w:left="1440" w:right="720" w:firstLineChars="140" /> </w:pPr> This set of indentations specifies that the first line should be indented 140 hundredths of a character units from the indentation specified for all remaining paragraphs, which is the 1440 twentieths of a point specified by the left attribute. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
hanging (Indentation Removed from First Line)	Specifies the indentation which shall be removed from the first line of the parent paragraph, by moving the indentation on the first line back towards the beginning of the direction of text flow. This indentation is specified relative to the paragraph indentation which is specified for all other lines in the parent paragraph. The firstLine and hanging attributes are mutually exclusive, if both are specified, then the firstLine value is ignored. If the hangingChars attribute is also specified, then this value is ignored. If this attribute is omitted, its value shall be assumed to be zero (if needed). [*Example*: Consider the following WordprocessingML fragment: <w:pPr> <w:ind w:left="1440" w:right="720" w:hanging="720" /> </w:pPr> This set of indentations specifies that the first line should be indented 720 twentieths of a point (one inch) towards the text margin from the indentation specified for all remaining paragraphs, which is the 1440 twentieths of a point specified by the left attribute. This gives the first line a one-half inch indentation from the text margin. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).
hangingChars (Indentation Removed From First Line in Character Units)	Specifies the indentation which shall be removed from the first line of the parent paragraph, by moving the indentation on the first line back towards the beginning of the direction of text flow. This indentation is specified relative to the paragraph indentation which is specified for all other lines in the parent paragraph. It is specified in one hundredths of a character unit. The firstLineChars and hangingChars attributes are mutually exclusive, if both are specified, then the firstLine value is ignored. If the hanging attribute is also specified,

Attributes	Description

	then its value is superseded by this value. If this attribute is omitted, its value shall be assumed to be zero (if needed).
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:ind w:left="1440" w:right="720" w:hangingChars="100" />`
	`</w:pPr>`
	
	This set of indentations specifies that the first line should be indented one character unit towards the text margin from the indentation specified for all remaining paragraphs, which is the 1440 twentieths of a point specified by the left attribute. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

left (Left Indentation)	Specifies the indentation which shall be placed between the left text margin for this paragraph and the left edge of that paragraph's content in a left to right paragraph, and the right text margin and the right edge of that paragraph's text in a right to left paragraph. If the mirrorIndents property (§2.3.1.18) is specified for this paragraph, then this indent is used for the inside page edge - the right page edge for odd numbered pages and the left page edge for even numbered pages.
	
	If this attribute is omitted, its value shall be assumed to be zero.
	
	All other values for this element are relative to the text margin, Negative values are defined such that the text is moved past the text margin, positive values move the text inside the text margin. This value may be superseded for the first line only via use of the firstLine or hanging attributes. As well, if the leftChars attribute is specified, then this value is ignored.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:ind w:left="720" w:right="2880" />`
	`</w:pPr>`
	
	This set of paragraph indentations specifies that this paragraph's text should be indented 720 twentieths of a point (one half inch) from the left text margin in this document, assuming this is a left to right paragraph. *end example*]
	
	The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

leftChars (Left Indentation in Character Units)	Specifies the indentation which shall be placed between the left text margin for this paragraph and the left edge of that paragraph's content in a left to right paragraph, and the right text margin and the right edge of that paragraph's text in a right to left paragraph. If the mirrorIndents property (§2.3.1.18) is specified for this paragraph, then

Attributes	Description

	this indent is used for the inside page edge - the right page edge for odd numbered pages and the left page edge for even numbered pages.
	
	This value is specified in hundredths of a character unit.
	
	If this attribute is omitted, its value shall be assumed to be zero.
	
	All other values for this element are relative to the text margin, Negative values are defined such that the text is moved past the text margin, positive values move the text inside the text margin. This value may be superseded for the first line only via use of the firstLine or hanging attributes. As well, if the left attribute is specified, then its value is ignored, and is superseded by this value.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:ind w:leftChars="250" />`
	`</w:pPr>`
	
	This set of paragraph indentations specifies that this paragraph's text should be indented two and a half character units from the left text margin in this document. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

right (Right Indentation)	Specifies the indentation which shall be placed between the right text margin for this paragraph and the right edge of that paragraph's content in a left to right paragraph, and the left text margin and the left edge of that paragraph's text in a right to left paragraph. If the mirrorIndents property (§2.3.1.18) is specified for this paragraph, then this indent is used for the outside page edge - the left page edge for odd numbered pages and the right page edge for even numbered pages.
	
	If this attribute is omitted, its value shall be assumed to be zero.
	
	All other values for this element are relative to the text margin, Negative values are defined such that the text is moved past the text margin, positive values move the text inside the text margin. As well, if the rightChars attribute is specified, then this value is ignored.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:ind w:left="720" w:right="-1440" />`
	`</w:pPr>`
	
	This set of paragraph indentations specifies that this paragraph's text should be indented 1440 twentieths of a point (one inch) into the right text margin in this document,

Attributes	Description
	assuming this is a left to right paragraph. *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

rightChars (Right Indentation in Character Units)	Specifies the indentation which shall be placed between the right text margin for this paragraph and the right edge of that paragraph's content in a left to right paragraph, and the left text margin and the left edge of that paragraph's text in a right to left paragraph. If the mirrorIndents property (§2.3.1.18) is specified for this paragraph, then this indent is used for the outside page edge - the left page edge for odd numbered pages and the right page edge for even numbered pages.
	
	This value is specified in hundredths of a character unit.
	
	If this attribute is omitted, its value shall be assumed to be zero.
	
	All other values for this element are relative to the right text margin, Negative values are defined such that the text is moved past the text margin, positive values move the text inside the text margin. As well, if the right attribute is specified, then its value is ignored, and is superseded by this value.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:ind w:rightChars="250" />`
	`</w:pPr>`
	
	This set of paragraph indentations specifies that this paragraph's text should be indented two and a half character units from the right text margin in this document, assuming this is a left to right paragraph. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Ind">
   <attribute name="left" type="ST_SignedTwipsMeasure" use="optional"/>
   <attribute name="leftChars" type="ST_DecimalNumber" use="optional"/>
   <attribute name="right" type="ST_SignedTwipsMeasure" use="optional"/>
   <attribute name="rightChars" type="ST_DecimalNumber" use="optional"/>
   <attribute name="hanging" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="hangingChars" type="ST_DecimalNumber" use="optional"/>
   <attribute name="firstLine" type="ST_TwipsMeasure" use="optional"/>
   <attribute name="firstLineChars" type="ST_DecimalNumber" use="optional"/>
</complexType>
```

2.3.1.13 jc (Paragraph Alignment)

This element specifies the paragraph alignment which shall be applied to text in this paragraph.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no alignment is applied to the paragraph.

[*Example*: Consider a paragraph which should be right justified to the right page side paragraph extents within a document. This constraint is specified in the following WordprocessingML content:

```
<w:pPr>
  <w:jc w:val="right" />
</w:pPr>
```

The paragraph is now `right` justified on the page. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description

val (Alignment Type)	Specifies the justification which should be applied to the parent object within a document.
	
	The possible values (see below) for this attribute are always specified relative to the page, and do not change semantic from right-to-left and left-to-right documents.
	
	[*Example*: Consider the following WordprocessingML fragment for a paragraph in a document:
	
	`<w:pPr>`
	`  <w:jc w:val="right" />`
	`</w:pPr>`
	
	This paragraph is now right justified on the page, regardless of the paragraph or section settings. *end example*]
	
	The possible values for this attribute are defined by the ST_Jc simple type (§2.18.50).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Jc">
   <attribute name="val" type="ST_Jc" use="required"/>
</complexType>
```

2.3.1.14 keepLines (Keep All Lines On One Page)

This element specifies that when rendering this document in a page view, all lines for this page are maintained on a single page whenever possible.

This means that if the contents of the current paragraph would normally span across two pages due to the placement of the paragraph's text, all lines in this paragraph shall be moved onto the next page to ensure they are displayed together. If this is not possible because all lines in the paragraph would exceed a single page in any case, then lines in this paragraph shall start on a new page, with page breaks as needed afterwards.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then this property shall not be applied.

[*Example*: Consider a WordprocessingML document in which a code fragment (such as the schema fragments in this document) are defined such that they should never be broken across a page boundary in order to improve readability. This constraint would be specified using the following paragraph properties in WordprocessingML:

```
<w:pPr>
  <w:keepLines />
  ...
</w:pPr>
```

This setting ensures that the schema fragment will be displayed on one page if possible. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

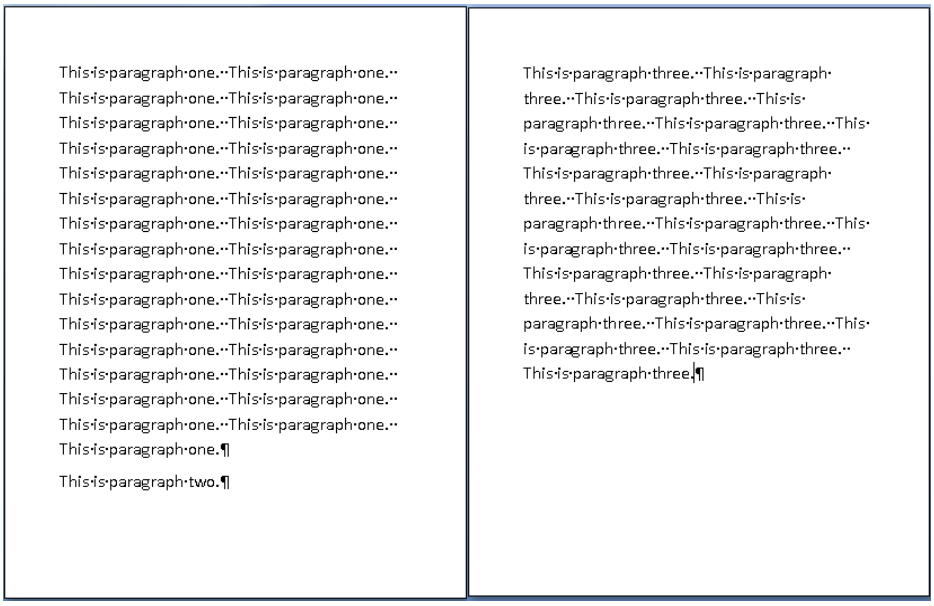
2.3.1.15 keepNext (Keep Paragraph With Next Paragraph)

This element specifies that when rendering this document in a paginated view, the contents of this paragraph are at least partly rendered on the same page as the following paragraph whenever possible.

This means that if the contents of the current paragraph would normally be completely rendered on a different page than the following paragraph (because only one of the two paragraphs would fit on the remaining space on the first page), then both paragraphs shall be rendered on a single page. This property can be chained between multiple paragraphs to ensure that all paragraphs are rendered on a single page without any intervening page boundaries. If this is not possible the entire set of paragraphs that are grouped together using this property would exceed a single page in any case, then the set of "keep with next" paragraphs shall start on a new page, with page breaks as needed afterwards.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then this property shall not be applied.

[*Example*: Consider the following document with three paragraphs:

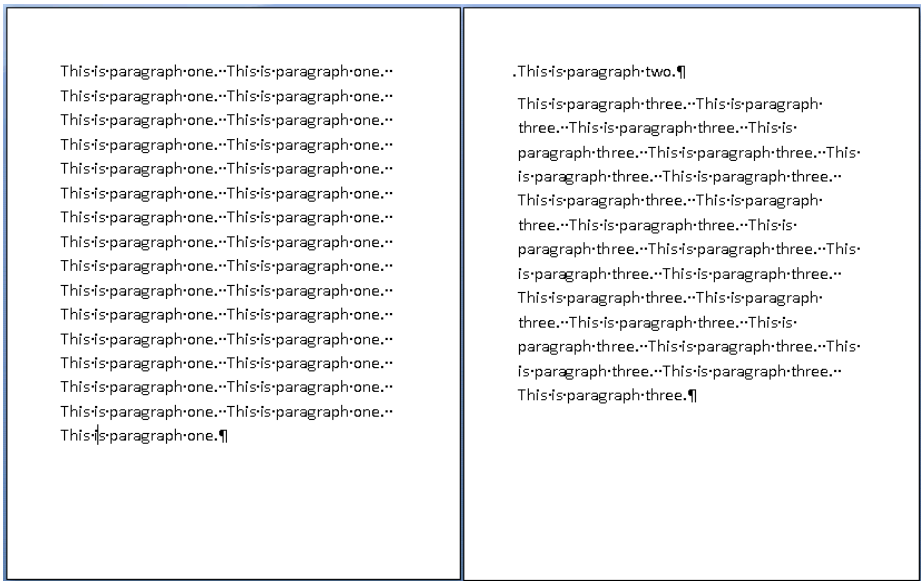


As shown above, the second paragraph and third paragraph are being rendered on two separate pages. However, a producer can specify that the second paragraph should not be displayed without any part of the third by setting the keepNext element as follows:

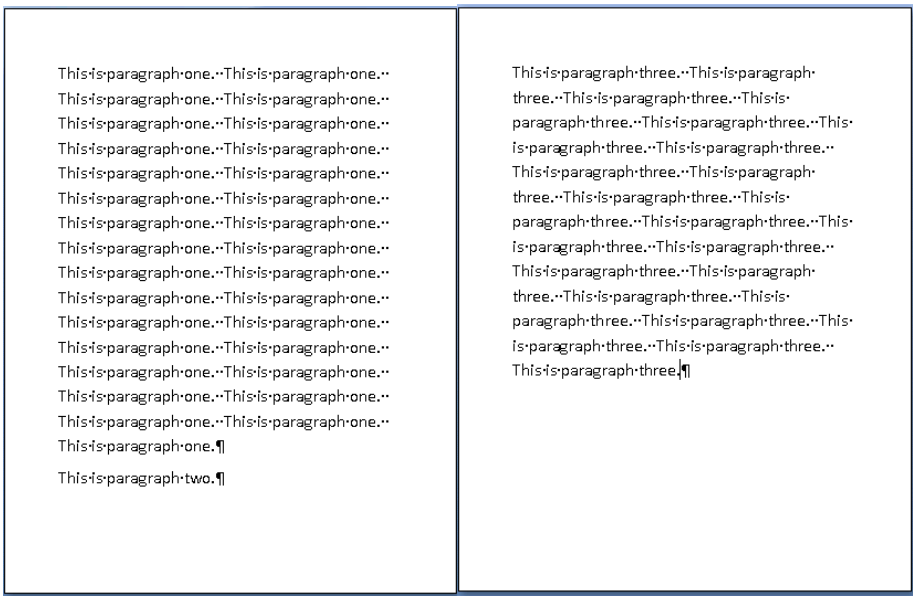
```
<w:pPr>
  <w:keepNext/>
```

```
    ...
  </w:pPr>
```

This would ensure that the second paragraph is displayed on the same page as the third paragraph:



However, if the first paragraph was also set to keepNext, then this set of grouped paragraphs would exceed a page, therefore the set of paragraphs would be grouped and start on the first page, resulting in the second paragraph reappearing on page one:



Since the paragraphs cannot all be put on one page, they all start on page one and flow as needed. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.16 kinsoku (Use East Asian Typography Rules for First and Last Character per Line)

This element specifies whether East Asian typography and line-breaking rules shall be applied to text in this paragraph to determine which characters may begin and end each line. This property only applies to Chinese PRC, Chinese Taiwan, and Japanese text in this paragraph.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then this property shall be applied to Chinese PRC, Chinese Taiwan, and Japanese text in this paragraph.

If these rules are set on the current paragraph, then the following rules are applied to the all first and last characters in the paragraph except the first and last character in the paragraph. By default, the following settings are used for kinsoku paragraphs:

Chinese (Simplified)

Annex A. Cannot start a line:

!%),.:;>?]}¢¨° • ˇ ¯ — ‖ ’ ” … ‰ ′ ″ › ℃ ： 、 。 〃 〉 》 」 』 】 〕 〗 ″ ﹀ ﹂ ﹀ ﹀ ﹏ ） ｝ 〕 ！ " % ′ ） ， ． ： ； ？ ］ ‘ | } ～ ¢

Annex B. Cannot end a line:

$([{£¥·‘“〈《「『【〔〖〝｛（〈$.[{

Chinese (Traditional)

Annex C. Cannot start a line:

!),.:;?]}¢• －—

’ ” •‥…… ′ － 、 。〉 》 」 』 】 ） ″ ： || ｜ ﹀﹀﹀﹀﹀﹀﹀﹏ ，、 ． ； ： ？

！ ） ｝ ） ！ ） ， ． ： ； ？ ］ ｜ ｝ 、

Annex D. Cannot end a line:

([{£¥ ‘ “ 〝 〈 《 「 『 【 〔 〝﹀﹀﹀﹀﹀﹀﹀﹀（ ｛ （ （ ｛

Japanese

Annex E. Cannot start a line:

!%),.:;?]}¢° ’ ” ‰′ ″ ℃、。々〉 》 」 』 】 〕 ゛ ゜ヽゝ・ ヽゝ！ ％），． ： ；

？ ］ ｝ 。」、・ﾞﾟ ₡

Annex F. Cannot end a line:

$([\{£¥ ‘ “ 〈 《 「 『 【 〔 $ （ ［ {「₤￥

Korean

Annex G. Cannot start a line:

!%),.:;?]}¢° ’ ” ′ ″ ℃〉 》 」 』 】 〕 ！ ％），． ： ； ？ ］ } ₡

Annex H. Cannot end a line:

$([\{£¥ ‘ “ 〈 《 「 『 【 〔 $ （ ［ {₤￥₩

If the strictFirstAndLastChars property (§2.15.1.83) is set in the Document Settings part, then the following settings supersede the defaults for Japanese:

Annex I. Cannot start a line:

!%),.:;?]}¢° ’ ” ‰′ ″ ℃、。々〉 》 」 』 】 〕 ぁ ぃ ぅ ぇ ぉ っ ゃ ゅ ょ ゎ ゛ ゜ヽゝ

ァ ィ ゥ ェ ォ ッ ャ ュ ョ ヮ カ ケ・ ー ヽゝ！ ％），． ： ； ？ ］ } 。」、・ｱｲｳｴｵﾔﾕﾖﾂｰﾞﾟ ₡

Annex J. Cannot end a line:

$([\{£¥ ‘ “ 〈 《 「 『 【 〔 $ （ ［ {「₤￥

If the noLineBreaksBefore property (§2.15.1.59) is set in the Document Settings part, then the characters it specifies cannot begin a line for the specified language. If the noLineBreaksAfter property (§2.15.1.58) is set in the Document Settings part, then the characters it specifies cannot end a line for the specified language. In both cases, those settings shall supersede the defaults specified above.

[*Example*: Consider a document with a paragraph which should not use the kinsoku line breaking properties. This paragraph would define the following WordprocessingML:

```
<w:pPr>
  <w:kinsoku w:val="off" />
</w:pPr>
```

This paragraph would now be exempt from any kinsoku line breaking rules, and the characters specified above are allowed to begin and end lines as they normally would. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.17 left (Left Paragraph Border)

This element specifies the border which shall be displayed on the left side of the page around the specified paragraph.

To determine if any two adjoining paragraphs should have a left border which spans the full line height or not, the left border shall be drawn between the top border or between border at the top (whichever would be rendered for the current paragraph), and the bottom border or between border at the bottom (whichever would be rendered for the current paragraph).

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no left border shall be applied.

[*Example*: Consider the following two paragraphs' WordprocessingML definition:

```
<w:p>
  <w:pPr>
```

```
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>First paragraph.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>Second paragraph.</w:t>
  </w:r>
</w:p>
```

Since the paragraph border set is identical between the two paragraphs, the paragraphs are connected by a between border. These paragraphs will therefore draw the left border between the top and between borders for the first paragraph, and the between and bottom borders for the second paragraph. *end example*]

Parent Elements
pBdr (§2.3.1.24)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is true, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the

Attributes	Description
	following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value. [*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:

Attributes	Description
	<w:top w:val="dashed" w:sz="24" …/> <w:left w:val="dashed" w:sz="24" …/> <w:bottom w:val="dashed" w:sz="24" …/> <w:right w:val="dashed" w:sz="24" …/> The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).
themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup: <w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is

Attributes	Description
	calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}^{'} = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L^{'} = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border.

Attributes	Description
	The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object.

Attributes	Description
	This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.3.1.18 mirrorIndents (Use Left/Right Indents as Inside/Outside Indents)

This element specifies whether the paragraph indents should be interpreted as mirrored indents. When this element is present, the left indent shall become the inside indent and the right indent shall become the outside indent.

If the mirrorIndents property is specified for this paragraph, then the inside page edge is the right page edge for odd numbered pages and the left page edge for even numbered pages. Conversely, the outside page edge is the left page edge for odd numbered pages and the right page edge for even numbered pages.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then this property shall not be applied.

[*Example*: Consider a paragraph on the first page of a document which should have a one inch indentation from the text margins on the inside edge when the resulting document is printed and bound. This means that the paragraph will have a one inch right border if it is on an odd numbered page, and a one inch left border if it is on an even numbered page. This set of indentations is specified using the following WordprocessingML:

```
<w:pPr>
  <w:ind w:left="1440" />
  <w:mirrorIndents />
```

```
</w:pPr>
```

This set of indentation properties specifies that a 1440 twip indentation should be provided on the left side of the text margins for this paragraph. However, since the mirrorIndents property is set, the left indent is really the inside indent, and if this paragraph is on page one, shall result in a one inch right indent from the text margin. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.19 numPr (Numbering Definition Instance Reference)

This element specifies that the current paragraph references a *numbering definition instance* in the current document.

The presence of this element specifies that the paragraph will inherit the properties specified by the numbering definition in the num element (§2.9.16) at the level specified by the level specified in the lvl element (§2.9.7) and shall have an associated number positioned before the beginning of the text flow in this paragraph. When this element appears as part of the paragraph formatting for a paragraph style, then any numbering level defined using the ilvl element shall be ignored, and the pStyle element (§2.9.25) on the associated abstract numbering definition shall be used instead.

[*Example*: Consider a paragraph in a document which should be associated with level 4 of a numbering definition with ID 0. Associating the paragraph with this numbering definition would be specified using the following WordprocessingML:

```
<w:pPr>
  <w:numPr>
    <w:ilvl w:val="4" />
    <w:numId w:val="0" />
  </w:numPr>
</w:pPr>
```

The numPr element specifies that this paragraph shall contain numbering information, and its children specify that the numbering definition for that numbering information shall have a numId of 0 and an ilvl of 4 within that numbering definition. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Child Elements	Subclause
ilvl (Numbering Level Reference)	§2.9.3
ins (Inserted Numbering Properties)	§2.13.5.19
numberingChange (Previous Paragraph Numbering Properties)	§2.13.5.30
numId (Numbering Definition Instance Reference)	§2.9.19

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_NumPr">
   <sequence>
      <element name="ilvl" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="numId" type="CT_DecimalNumber" minOccurs="0"/>
      <element name="numberingChange" type="CT_TrackChangeNumbering" minOccurs="0"/>
      <element name="ins" type="CT_TrackChange" minOccurs="0"/>
   </sequence>
</complexType>
```

2.3.1.20 outlineLvl (Associated Outline Level)

This element specifies the *outline level* which shall be associated with the current paragraph in the document. The *outline level* specifies an integer which defines the level of the associated text. This level shall not affect the appearance of the text in the document, but shall be used to calculate the TOC field (§2.16.5.75) if the appropriate field switches have been set, and may be used by consumers to provide additional application behavior.

The outline level of text in the document (specified using the val attribute) may be from 0 to 9, where 9 specifically indicates that there is no outline level specifically applied to this paragraph. If this element is omitted, then the outline level of the content is assumed to be 9 (no level).

[*Example*: Consider a paragraph in a document which has outline level 1 applied to it. This paragraph would specify the following WordprocessingML:

```
<w:pPr>
  <w:outlineLvl w:val="0" />
</w:pPr>
```

This paragraph is now of outline level 1, and if a table of contents field is inserted that utilizes outlines levels, the text in this paragraph will be at level one in the TOC. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.3.1.21 overflowPunct (Allow Punctuation to Extent Past Text Extents)

This element specifies that punctuation characters which appear at the end of text in any line in this paragraph shall be allowed to extend one character past the text extents (indents/margins) as needed in order to ensure that they are not displayed as hanging punctuation. *Hanging punctuation* is defined as punctuation which appears on a different line than the text which it logically would appear with.

Omitting this element sets its value to `true`.

[*Example*: Consider a WordprocessingML document with the following string at the end of a line:

```
"This is some text in quotation marks"
```

Typically, if the text extents would normally fall between the letter s and the closing quotation mark, the quotation mark would be allowed to extend past the end of the line by one character even though the punctuation is not part of the word `marks` (since the omission of overflowPunct is equivalent to setting its val attribute to `true`).

However, if this behavior should not be applied to this paragraph, a producer can specify this by setting the property in the WordprocessingML:

```
<w:pPr>
  <w:overflowPunct w:val="0" />
</w:pPr>
```

The line would now break after the letter `s`, regardless of the fact that the next character is a quotation mark. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.22 p (Paragraph)

This element specifies a paragraph of content in the document.

The contents of a paragraph in a WordprocessingML document shall consist of any combination of the following four types of content:

- Paragraph properties
- Annotations (bookmarks, comments, revisions)
- Custom markup
- Run level content (fields, hyperlinks, runs)

[*Example*: Consider a basic WordprocessingML document with a single paragraph. This paragraph would be expressed as follows:

```
<w:document>
  <w:body>
    <w:p>
      <w:r>
        <w:t>Text</w:t>
      </w:r>
      <w:fldSimple w:instr="AUTHOR">
        <w:r>
          <w:t>Author Name</w:t>
        </w:r>
      </w:fldSimple>
    </w:p>
  </w:body>
</w:document>
```

The p element is the container for all of the content in the paragraph, which in this example includes both a text run and a simple field. *end example*]

Parent Elements

Attributes	Description
rsidDel (Revision Identifier for Paragraph Deletion)	Specifies a unique identifier used to track the editing session when the paragraph was deleted from the main document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between

Attributes	Description
	subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidP (Revision Identifier for Paragraph Properties)	This attribute specifies a unique identifier used to track the editing session when the paragraph's properties were last modified in this document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidR (Revision Identifier for Paragraph)	This attribute specifies a unique identifier used to track the editing session when the paragraph was added to the main document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidRDefault (Default Revision Identifier for Runs)	This attribute specifies a unique identifier used for all runs in this paragraph which do not explicitly declare an rsidR attribute. This attribute allows consumers to optimize the locations where rsid* values are written in this document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document.

Attributes	Description
	The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidRPr (Revision Identifier for Paragraph Glyph Formatting)	This attribute specifies a unique identifier used to track the editing session when the glyph character representing the paragraph mark was last modified in the main document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_P">
    <sequence>
        <element name="pPr" type="CT_PPr" minOccurs="0"/>
        <group ref="EG_PContent" minOccurs="0" maxOccurs="unbounded"/>
    </sequence>
    <attribute name="rsidRPr" type="ST_LongHexNumber"/>
    <attribute name="rsidR" type="ST_LongHexNumber"/>
    <attribute name="rsidDel" type="ST_LongHexNumber"/>
    <attribute name="rsidP" type="ST_LongHexNumber"/>
    <attribute name="rsidRDefault" type="ST_LongHexNumber"/>
</complexType>
```

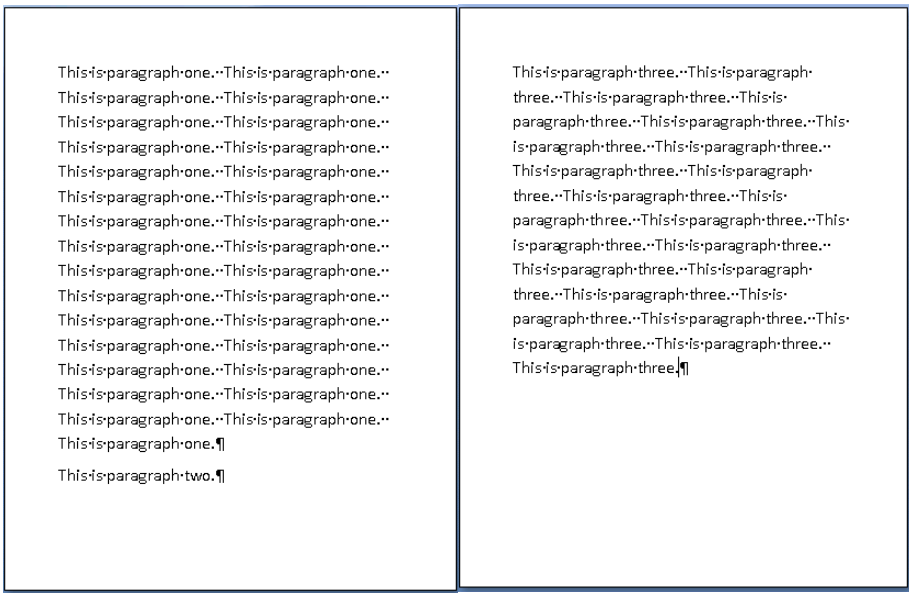
2.3.1.23 pageBreakBefore (Start Paragraph on Next Page)

This element specifies that when rendering this document in a paginated view, the contents of this paragraph are rendered on the start of a new page in the document.

This means that if the contents of the current paragraph would normally be rendered on the middle of a page in the host document, then the paragraph shall be rendered on a new page as if the paragraph was preceded by a page break in the WordprocessingML contents of the document. This property supersedes any use of the keepNext property, so that if any paragraph wishes to be on the same page as this paragraph, they will still be separated by a page break.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then this property shall not be applied.

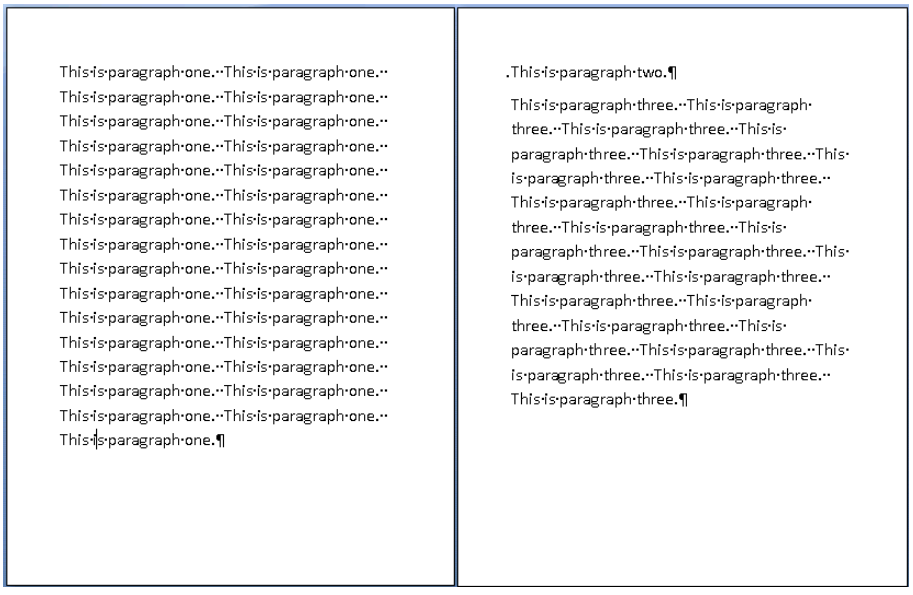
[*Example*: Consider the following document with three paragraphs:



As shown above, the second paragraph is rendered at the bottom of page one. However, a producer can specify that the second paragraph should be displayed at the top of a new page by setting the pageBreakBefore element as follows:

```
<w:pPr>
  <w:pageBreakBefore/>
</w:pPr>
```

This would ensure that the second paragraph is displayed on a new page:



Since the paragraph is specified to start on a new page, it begins page two even though it could have fit on page one. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.24 pBdr (Paragraph Borders)

This element specifies the borders for the parent paragraph. Each child element shall specify a specific type of border (left, right, bottom, top, and between).

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no paragraph borders shall be applied.

[*Example*: Consider a pairing of paragraphs which have a three point red border around them, and a six point border between them. These paragraphs would each have the following set of paragraph borders:

```
<w:pBdr>
  <w:top w:val="single" w:sz="24" w:space="1" w:color="FF0000" />
  <w:left w:val="single" w:sz="24" w:space="4" w:color="FF0000" />
  <w:bottom w:val="single" w:sz="24" w:space="1" w:color="FF0000" />
  <w:right w:val="single" w:sz="24" w:space="4" w:color="FF0000" />
```

```
    <w:between w:val="single" w:sz="48" w:space="1" w:color="4D5D2C" />
  </w:pBdr>
```

The resulting paragraphs have identical pBdr values, therefore they would use the top, left, bottom, and right borders around them as a units, and the between border between each other. This matching heuristic is further discussed in the child elements of the pBdr element. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Child Elements	Subclause
bar (Paragraph Border Between Facing Pages)	§2.3.1.4
between (Paragraph Border Between Identical Paragraphs)	§2.3.1.5
bottom (Paragraph Border Between Identical Paragraphs)	§2.3.1.7
left (Left Paragraph Border)	§2.3.1.17
right (Right Paragraph Border)	§2.3.1.28
top (Paragraph Border Above Identical Paragraphs)	§2.3.1.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PBdr">
   <sequence>
      <element name="top" type="CT_Border" minOccurs="0"/>
      <element name="left" type="CT_Border" minOccurs="0"/>
      <element name="bottom" type="CT_Border" minOccurs="0"/>
      <element name="right" type="CT_Border" minOccurs="0"/>
      <element name="between" type="CT_Border" minOccurs="0"/>
      <element name="bar" type="CT_Border" minOccurs="0"/>
   </sequence>
</complexType>
```

2.3.1.25 pPr (Previous Paragraph Properties)

This element specifies a set of paragraph properties which shall be attributed to a revision by a particular author and at a particular time. This element contains the set of properties which have been tracked as a specific set of revisions by one author.

[*Example*: Consider a paragraph which should have a set of paragraph formatting properties that were added with revision tracking turned on. This set of revised properties is specified in the paragraph properties as follows:

```
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:bottom w:val="single" w:sz="8" w:space="4" w:color="4F81BD" />
```

```
      </w:pBdr>
      <w:pPrChange w:author="user1" … >
        <w:pPr>
          <w:spacing w:after="300" />
          <w:contextualSpacing />
        </w:pPr>
      </w:pPrChange>
    </w:pPr>
  </w:p>
```

The pPr element under pPrChange specifies the properties which are applied to the current paragraph with revision tracking turned on - in this case, spacing after the paragraph using the spacing element (§2.3.1.33), and that spacing should be ignored for paragraphs above/below of the same style using the contextualSpacing element (§2.3.1.9). *end example*]

   </sequence>
</complexType>
```

2.3.1.26 pPr (Paragraph Properties)

This element specifies a set of paragraph properties which shall be applied to the contents of the parent paragraph after all style/numbering/table properties have been applied to the text. These properties are defined as *direct formatting*, since they are directly applied to the paragraph and supersede any formatting from styles.

[*Example*: Consider a paragraph which should have a set of paragraph formatting properties. This set of properties is specified in the paragraph properties as follows:

```
<w:p>
  <w:pPr>
    <w:pBdr>
```

```
      <w:bottom w:val="single" w:sz="8" w:space="4" w:color="4F81BD" />
    </w:pBdr>
    <w:spacing w:after="300" />
    <w:contextualSpacing />
  </w:pPr>
</w:p>
```

The pPr element specifies the properties which are applied to the current paragraph - in this case, a bottom paragraph border using the bottom element (§2.3.1.7), spacing after the paragraph using the spacing element (§2.3.1.33), and that spacing should be ignored for paragraphs above/below of the same style using the contextualSpacing element (§2.3.1.9). *end example*]

<complexType name="CT_PPr">
   <complexContent>
      <extension base="CT_PPrBase">
         <sequence>
            <element name="rPr" type="CT_ParaRPr" minOccurs="0"/>
            <element name="sectPr" type="CT_SectPr" minOccurs="0"/>
            <element name="pPrChange" type="CT_PPrChange" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.3.1.27 pStyle (Referenced Paragraph Style)

This element specifies the style ID of the paragraph style which shall be used to format the contents of this paragraph.

This formatting is applied at the following location in the *style hierarchy*:

- Document defaults
- Table styles
- Numbering styles
- Paragraph styles (this element)
- Character styles
- Direct Formatting

This means that all properties specified in the style element (§2.7.3.17) with a styleId which corresponds to the value in this element's val attribute are applied to the paragraph at the appropriate level in the hierarchy.

If this element is omitted, or it references a style which does not exist, then no paragraph style shall be applied to the current paragraph. As well, this property is ignored if the paragraph properties are part of a paragraph style.

[*Example*: Consider the following WordprocessingML fragment:

```
<w:pPr>
  <w:pStyle w:val=”TestParagraphStyle” />
  <w:ind w:left=”1440” />
</w:pPr>
```

This paragraph specifies that it will inherit all of the paragraph properties specified by the paragraph style with a styleId of `TestParagraphStyle`, which will then have any indentation properties overridden with a left indentation of `1440` twentieths of a point, and no indentation for any other value. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.3.1.28 right (Right Paragraph Border)

This element specifies the border which shall be displayed on the right side of the page around the specified paragraph.

To determine if any two adjoining paragraphs should have a right border which spans the full line height or not, the right border shall be drawn between the top border or between border at the top (whichever would be rendered for the current paragraph), and the bottom border or between border at the bottom (whichever would be rendered for the current paragraph).

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no right border shall be applied.

[*Example*: Consider the following two paragraphs' WordprocessingML definition:

```
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>First paragraph.</w:t>
  </w:r>
</w:p>
<w:p>
```

```
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>Second paragraph.</w:t>
  </w:r>
</w:p>
```

Since the paragraph border set is identical between the two paragraphs, the paragraphs are connected by a between border. These paragraphs will therefore draw the right border between the top and between borders for the first paragraph, and the between and bottom borders for the second paragraph. *end example*]

Parent Elements
pBdr (§2.3.1.24)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value.

Attributes	Description
	The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.

Attributes	Description

	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:

Attributes	Description
	<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D.

Attributes	Description
	The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L^{'} = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $T_{xml} = 0.6 * 255$ $= 153$ $= 99(hex)$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}^{'} = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$ • Convert the resultant HSL color to RGB

Attributes	Description
	[*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L' = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.3.1.29 rPr (Run Properties for the Paragraph Mark)

This element specifies the set of run properties applied to the glyph used to represent the physical location of the paragraph mark for this paragraph. This paragraph mark, being a physical character in the document, can be formatted, and therefore must be capable of representing this formatting like any other character in the document.

If this element is not present, the paragraph mark is unformatted, as with any other run of text.

[*Example*: Consider a run of text displayed as follows, including a display format using the pilcrow sign ¶ for the paragraph mark glyph:

```
This is some text and the paragraph mark.¶
```

If we format the display formatting for the paragraph mark by making it red and giving it a 72 point font size, then the WordprocessingML shall reflect this formatting on the paragraph as follows:

```
<w:pPr>
  <w:rPr>
    <w:color w:val="FF0000" />
    <w:sz w:val="144" />
  </w:rPr>
</w:pPr>
```

The paragraph glyph's formatting is stored in the rPr element under the paragraph properties, since there is no run saved for the paragraph mark itself. *end example*]

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ParaRPr">
   <sequence>
      <group ref="EG_ParaRPrTrackChanges" minOccurs="0"/>
      <group ref="EG_RPrBase" minOccurs="0"/>
      <element name="rPrChange" type="CT_ParaRPrChange" minOccurs="0"/>
   </sequence>
</complexType>
```

2.3.1.30 rPr (Previous Run Properties for the Paragraph Mark)

This element specifies a set of run properties applied to the glyph used to represent the physical location of the paragraph mark for this paragraph which shall be attributed to a revision by a particular author and at a particular time. This element contains the set of properties which have been tracked as a specific set of revisions by one author.

[*Example*: Consider a run which has a set of run formatting properties that were added with revision tracking turned on. This set of revised properties is specified in the run properties as follows:

```
<w:p>
  <w:pPr>
    <w:rPr>
      <w:b />
      <w:imprint />
      <w:lang w:val="en-ca" />
      <w:rPrChange w:author="user1">
        <w:rPr>
          <w:i />
          <w:dstrike w:val="false" />
        </w:rPr>
      </w:rPrChange>
    </w:rPr>
  </w:pPr>
</w:p>
```

The rPr element under rPrChange specifies the properties which are applied to the run representing the paragraph mark before the revision tracking was turned on - in this case, italics using the i element (§2.3.2.14), and that any double strikethrough which was applied based on the style hierarchy shall be turned off using the dstrike element (§2.3.2.7). *end example*]

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_ParaRPrOriginal">
   <sequence>
      <group ref="EG_ParaRPrTrackChanges" minOccurs="0"/>
      <group ref="EG_RPrBase" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.3.1.31 shd (Paragraph Shading)

This element specifies the shading applied to the contents of the paragraph.

This shading consists of three components:

- Background Color
- (optional) Pattern
- (optional) Pattern Color

The resulting shading is applied by setting the background color behind the paragraph, then applying the pattern color using the mask supplied by the pattern over that background.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no paragraph shading shall be applied.

[*Example*: Consider a paragraph which shall have a background consisting of a theme color `accent3` with a theme color `accent6` overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:

```
<w:pPr>
  <w:shd w:val="pct20" w:themeColor="accent6" w:themeFill="accent3" />
</w:pPr>
```

The resulting paragraph will use the background color `accent3` under the foreground pattern color `accent6` as specified by the `pct20` pattern mask. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
color (Shading Pattern Color)	Specifies the color used for any foreground pattern specified for this shading using the val attribute. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the foreground shading color as appropriate. If the shading style (the val attribute) specifies the use of no shading format or is omitted, then this property has no effect. Also, if the shading specifies the use of a theme color via the themeColor attribute, then this value is superseded by the theme color value. If this attribute is omitted, then its value shall be assumed to be `auto`. [*Example*: Consider a shading of type `pct20` with a foreground color value of `auto`, as follows: `<w:shd w:val="pct20"... w:color="auto"/>` The foreground color for this shading pattern therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the shading color can be distinguished against the page's background color. *end example*] The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
fill (Shading Background Color)	Specifies the color used for the background for this shading. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the background shading color as appropriate. If this attribute is omitted, then its value shall be assumed to be `auto`.

Attributes	Description
	[*Example*: Consider a shading using a background color of hex value C3D69B, using the following WordprocessingML: `<w:shd w:fill="C3D69B" />` The background color for this shading therefore will be a color with a hex value of C3D69B. *end example*] If the shading specifies the use of a theme color via the themeFill attribute, then this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).

themeColor (Shading Pattern Theme Color)	Specifies a theme color which should be applied to any foreground pattern specified for this shading using the val attribute.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document.
	
	If this element is omitted, then no theme color is applied, and the color attribute shall be used to determine the shading pattern color.
	
	[*Example*: Consider a paragraph which shall have a background consisting of a theme color accent3 with a theme color accent6 overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:shd w:val="pct20" w:themeColor="accent6"`
	`w:themeFill="accent3" />`
	`</w:pPr>`
	
	The resulting paragraph will use the foreground pattern color accent6 in the region specified by the pct20 pattern mask. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeFill (Shading Background Theme Color)	Specifies a theme color which should be applied to the background for this shading. The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document. If this element is omitted, then no theme color is applied, and the color attribute shall be

Attributes	Description
	used to determine the shading background color. [*Example*: Consider a paragraph which shall have a background consisting of a theme color `accent3` with a theme color `accent6` overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML: `<w:shd w:val="pct20" w:themeColor="accent6" w:themeFill="accent3" />` The resulting shading will use the background color specified by the `accent3` theme color. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeFillShade (Shading Background Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this shading color. If the themeFillShade is supplied, then it is applied to the RGB value of the themeFill color (from the theme part) to determine the final color applied to this border. The themeFillShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $S_{xml} = 0.4 * 255$ $= 102$ $= 66(hex)$ The resulting themeFillShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `C0504D`. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$.

Attributes	Description
	Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L^{'} = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting shading's fill attribute: `<w:shd w:fill="943634" w:themeFill="accent2" w:themeFillShade="BF" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeFillTint (Shading Background Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeFillTint is supplied, then it is applied to the RGB value of the themeFill color (from the theme part) to determine the final color applied to this border. The themeFillTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $T_{xml} = 0.6 * 255$ $= 153$ $= 99(hex)$ The resulting themeFillTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}^{'} = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color,

Attributes	Description
	whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L^{'} = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting shading's fill attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:fill="95B3D7" w:themeFillColor="accent2" w:themeFillTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeShade (Shading Pattern Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this shading color. If the themeShade is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $S_{xml} = 0.4 * 255$ $= 102$ $= 66(hex)$ Te resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}^{'} = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$

Attributes	Description
	• Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `C0504D`. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L' = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get `943634`. This transformed value can be seen in the resulting background's color attribute: `<w:shd w:color="943634" w:themeColor="accent2" w:themeShade="BF" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Shading Pattern Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeTint is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $T_{xml} = 0.6 * 255$ $= 153$ $= 99(hex)$ The resulting themeTint value in the file format would be `99`. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1)

Attributes	Description
	• Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting shading's color attribute: `<w:shd w:color="95B3D7" w:themeColor="accent2" w:themeTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Shading Pattern)	Specifies the pattern which shall be used to lay the pattern color over the background color for this paragraph shading. This pattern consists of a mask which is applied over the background shading color to get the locations where the pattern color should be shown. Each of these possible masks are shown in the simple type values referenced below. [*Example*: Consider a shaded paragraph which uses a 10 percent foreground fill, resulting in the following WordprocessingML: `<w:shd w:val="pct10" .../>` This shading val is `pct10`, indicating that the border style is a 10 percent foreground fill mask. *end example*] The possible values for this attribute are defined by the ST_Shd simple type (§2.18.85).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Shd">
   <attribute name="val" type="ST_Shd" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="fill" type="ST_HexColor" use="optional"/>
   <attribute name="themeFill" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeFillTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeFillShade" type="ST_UcharHexNumber" use="optional"/>
</complexType>
```

2.3.1.32 snapToGrid (Use Document Grid Settings for Inter-Line Paragraph Spacing)

This element specifies whether the current paragraph should use the document grid lines per page settings defined in the docGrid element (§2.6.5) when laying out the contents in the paragraph. This setting determines whether the additional line pitch specified in the document grid shall be added to each line in this paragraph as specified by the document grid.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then the paragraph shall use the document grid to lay out text when a document grid is defined for this document.

[*Example*: Consider two single-spaced paragraphs in a section with a document grid set to allow 15 lines per page. This document grid would effectively specifies that an additional line pitch of 45.6 points shall be added to each line in order to ensure that the resulting page contains only 15 lines of text.

If this property is set on the first paragraph, but turned off on the second paragraph, as follows:

```
<w:p>
  <w:pPr>
    <w:snapToGrid w:val="off" />
  </w:pPr>
  ...
</w:p>
<w:p>
  ...
</w:p>
```

The resulting document shall have 45.6 points of additional line pitch added to each line in paragraph two, but zero lines of additional line pitch added to each line in paragraph one, since the snapToGrid property is turned off. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.33 spacing (Spacing Between Lines and Above/Below Paragraph)

This element specifies the inter-line and inter-paragraph spacing which shall be applied to the contents of this paragraph when it is displayed by a consumer.

If this element is omitted on a given paragraph, each of its values is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then the paragraph shall have no spacing applied to its lines, or above and below its contents.

[*Example*: Consider the following WordprocessingML paragraph:

```
<w:pPr>
  <w:spacing w:after="200" w:line="276" w:lineRule="auto" />
</w:pPr>
```

This paragraph specifies that it shall have at least 200 twentieths of a point after the last line in each paragraph, and that the spacing in each line should be automatically calculated based on a 1.15 times (276 divided by 240) the normal single spacing calculation. *end example*]

When determining the spacing between any two paragraphs, a consumer shall use the maximum of the inter-line spacing in each paragraph, the spacing after the first paragraph and the spacing before the second paragraph to determine the net spacing between the paragraphs.

[*Example*: Consider two consecutive single-spaced paragraphs in a document, the first of which specifies spacing below of 12 points, the second of which specifies spacing above of 4 points. These constraints are expressed using the following WordprocessingML:

```
<w:p>
  <w:pPr>
    <w:spacing w:after="240" />
  </w:pPr>
  …
</w:p>
<w:p>
  <w:pPr>
    <w:spacing w:before="80" />
  </w:pPr>
  …
</w:p>
```

The resulting spacing between the first and second paragraph will be 12 points, since that is the largest spacing requested between the two paragraphs. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description

after (Spacing Below Paragraph)	Specifies the spacing that should be added after the last line in this paragraph in the document in absolute units.
	
	If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then the paragraph shall have no spacing applied below its contents.
	
	If the afterLines attribute or the afterAutoSpacing attribute is also specified, then this attribute value is ignored.
	
	[*Example*: Consider the following WordprocessingML paragraph:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:spacing w:after="240" />`
	`  </w:pPr>`
	`  …`
	`</w:p>`

Attributes	Description
	This paragraph shall have a minimum spacing below its final lines of 240 twentieths of a point, although the actual spacing may be determined by the inter-line spacing or the spacing above the following paragraph, if either are greater. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

afterAutospacing (Automatically Determine Spacing Below Paragraph)	Specifies whether a consumer shall automatically determine the spacing after this paragraph based on its contents.
	
	This automatic spacing shall match the spacing which would be applied to the paragraph in an HTML document where no explicit spacing before/after is specified.
	
	If this attribute is specified, then any value in after or afterLines is ignored, and the spacing is automatically determined by the consumer.
	
	If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then automatic spacing is turned off (not applied).
	
	[*Example*: Consider a paragraph in a document whose spacing below shall automatically be determined by the consumer based on the paragraph's contents. This constraint would be specified by the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:spacing .. w:afterAutospacing="on" />`
	`</w:pPr>`
	
	The resulting paragraph shall have the spacing below its last line determined automatically by the consumer to match an HTML document as specified. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

afterLines (Spacing Below Paragraph in Line Units)	Specifies the spacing that should be added after the last line in this paragraph in the document in line units.
	
	The value of this attribute is specified in one hundredths of a line.
	
	If the afterAutoSpacing attribute is also specified, then this attribute value is ignored. If this setting is never specified in the style hierarchy, then its value shall be zero (if needed).
	
	[*Example*: Consider the following WordprocessingML paragraph:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:spacing w:afterLines="300" />`

Attributes	Description
	</w:pPr> ... </w:p> This paragraph shall have a minimum spacing below its final lines of 3 lines, although the actual spacing may be determined by the inter-line spacing or the spacing above the following paragraph, if either are greater. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).
before (Spacing Above Paragraph)	Specifies the spacing that should be added above the first line in this paragraph in the document in absolute units. If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then the paragraph shall have no spacing applied above its contents. If the beforeLines attribute or the beforeAutoSpacing attribute is also specified, then this attribute value is ignored. [*Example*: Consider the following WordprocessingML paragraph: <w:p> <w:pPr> <w:spacing w:before="80" /> </w:pPr> ... </w:p> This paragraph shall have a minimum spacing above its first line of 80 twentieths of a point, although the actual spacing may be determined by the inter-line spacing or the spacing below the last line in the preceding paragraph, if either are greater. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).
beforeAutospacing (Automatically Determine Spacing Above Paragraph)	Specifies whether a consumer shall automatically determine the spacing before this paragraph based on its contents. This automatic spacing shall match the spacing which would be applied to the paragraph in an HTML document where no explicit spacing before/after is specified. If this attribute is specified, then any value in before or beforeLines is ignored, and the spacing is automatically determined by the consumer. If this element is omitted on a given paragraph, its value is determined by the setting

Attributes	Description

	previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then automatic spacing is turned off (not applied).
	
	[*Example*: Consider a paragraph in a document whose spacing above shall automatically be determined by the consumer based on the paragraph's contents. This constraint would be specified by the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:spacing … w:beforeAutospacing="on" />`
	`</w:pPr>`
	
	The resulting paragraph shall have the spacing above its first line determined automatically by the consumer to match an HTML document as specified. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

beforeLines (Spacing Above Paragraph IN Line Units)	Specifies the spacing that should be added before the first line in this paragraph in the document in line units.
	
	The value of this attribute is specified in one hundredths of a line.
	
	If the beforeAutoSpacing attribute is also specified, then this attribute value is ignored. If this setting is never specified in the style hierarchy, then its value shall be zero (if needed).
	
	[*Example*: Consider the following WordprocessingML paragraph:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:spacing w:beforeLines="100" />`
	`  </w:pPr>`
	`  ...`
	`</w:p>`
	
	This paragraph shall have a minimum spacing above its first line of 1 line, although the actual spacing may be determined by the inter-line spacing or the spacing below the preceding paragraph, if either are greater. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

line (Spacing Between Lines in Paragraph)	This attribute specifies the amount of vertical spacing between lines of text within this paragraph. If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no line spacing

Attributes	Description

	shall be applied to lines within this paragraph.
	
	If the value of the lineRule attribute is either `atLeast` or `exactly`, then the value of this attribute shall be interpreted as twentieths of a point. When the value of the lineRule attribute is either `exactly`, the text shall be positioned as follows within that line height:
	• When the line height is too small, the text shall be positioned at the bottom of the line (i.e. clipped from the top down)
	• When the line height is too large, the text shall be centered in the available space.
	
	If the value of the lineRule attribute is `auto`, then the value of the line attribute shall be interpreted as 240ths of a line, in the manner described by the simple type's values.
	
	[Example: Consider the following WordprocessingML paragraph which should have an inter-line spacing of 1.15 times the line height. This constraint would be specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:spacing w:line="276" w:lineRule="auto" />`
	`</w:pPr>`
	
	The lineRule attribute value of `auto` specifies that the value of the line attribute is to be interpreted in 240ths of a single line height, which means that the net spacing is 276/240ths of a line or 1.15 lines tall. *end example*]
	
	The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

lineRule (Type of Spacing Between Lines)	Specifies how the spacing between lines is calculated as stored in the line attribute.
	
	If this attribute is omitted, then it shall be assumed to be of a value `auto` if a line attribute value is present.
	
	If the value of this attribute is either `atLeast` or `exactly`, then the value of the line attribute shall be interpreted as twentieths of a point, in the manner described by the simple type's values.
	
	If the value of this attribute is `auto`, then the value of the line attribute shall be interpreted as 240ths of a line, in the manner described by the simple type's values.
	
	[*Example*: Consider the following WordprocessingML paragraph which should have an inter-line spacing of 1.15 times the line height. This constraint would be specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:spacing w:line="276" w:lineRule="auto" />`

Attributes	Description
	</w:pPr> The lineRule attribute value of auto specifies that the value of the line attribute is to be interpreted in 240ths of a single line height. *end example*] The possible values for this attribute are defined by the ST_LineSpacingRule simple type (§2.18.55).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Spacing">
    <attribute name="before" type="ST_TwipsMeasure" use="optional"/>
    <attribute name="beforeLines" type="ST_DecimalNumber" use="optional"/>
    <attribute name="beforeAutospacing" type="ST_OnOff" use="optional"/>
    <attribute name="after" type="ST_TwipsMeasure" use="optional"/>
    <attribute name="afterLines" type="ST_DecimalNumber" use="optional"/>
    <attribute name="afterAutospacing" type="ST_OnOff" use="optional"/>
    <attribute name="line" type="ST_SignedTwipsMeasure" use="optional"/>
    <attribute name="lineRule" type="ST_LineSpacingRule" use="optional"/>
</complexType>
```

2.3.1.34 suppressAutoHyphens (Suppress Hyphenation for Paragraph)

This element specifies whether any hyphenation shall be performed on this paragraph by the consumer when requested using the autoHyphenation element (§2.15.1.10) in the document's settings. This element specifies whether the current paragraph should be exempted from any hyphenation which is applied by the consumer on this document.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then the default hyphenation settings for the document, as specified in the autoHyphenation element, shall apply to the contents of this paragraph.

[*Example*: Consider a document which shall be hyphenated automatically by a consumer, since it has the autoHyphenation element set to true in its document settings. If this paragraph should be exempted from that hyphenation pass, this requirement would be specified using the following WordprocessingML:

```
<w:pPr>
  <w:suppressAutoHyphens />
</w:pPr>
```

The paragraph would then be exempted from hyphenation by a consumer at display time, regardless of the hyphenation settings for the document. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.35 suppressLineNumbers (Suppress Line Numbers for Paragraph)

This element specifies whether line numbers shall be calculated for lines in this paragraph by the consumer when line numbering is requested using the lnNumType element (§2.6.8) in the paragraph's parent section settings. This element specifies whether the current paragraph's lines should be exempted from line numbering which is applied by the consumer on this document, not just suppressing the display of the numbering, but removing these lines from the line numbering calculation.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then the default line number settings for the section, as specified in the lnNumType element shall apply to each line of this paragraph.

[*Example*: Consider a document with three paragraphs, each of which are displayed on five lines , all contained in a section which has the lnNumType element specified. If the second paragraph should be exempted from that line numbering, this requirement would be specified using the following WordprocessingML:

```
<w:pPr>
  <w:suppressLineNumbers />
</w:pPr>
```

The paragraph would then be exempted from line by a consumer at display time, which would result in paragraph one using line numbers one through five, the second paragraph having no line numbers, and the third paragraph using line numbers six through ten. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.36 suppressOverlap (Prevent Text Frames From Overlapping)

This element specifies whether a text frame which intersects another text frame at display time shall be allowed to overlap the contents of the other text frame. If a text frame cannot overlap other text frames, it shall be repositioned when displayed to prevent this overlap as needed.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then overlap shall be allowed between a text frame which intersects another text frame displayed at the same location.

[*Example*: Consider a document with two text frames which are allowed to overlap each other. If the second text frame should overlap the contents of another text frame, that constraint would be specified via the following WordprocessingML:

```
<w:p>
  …
</w:p>
<w:p>
```

```
    <w:pPr>
      <w:framePr … />
      <w:suppressOverlap />
    </w:pPr>
    …
  </w:p>
```

The resulting text frame with the suppressOverlap property specified would never overlap any intersecting text frames. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.37 tab (Custom Tab Stop)

This element specifies a single custom tab stop within a set of custom tab stops applied as part of a set of customized paragraph properties in a document.

[*Example*: Consider a custom tab stops at 1.5" in a WordprocessingML document. This tab stop would be contained within a tab element defining the tab stop as follows:

```
<w:tab w:val="left" w:pos="2160" />
```

The tab element specifies all of the properties for the customized tab stop for the current paragraph property set. *end example*]

Parent Elements
tabs (§2.3.1.38)

Attributes	Description
leader (Tab Leader Character)	Specifies the character which shall be used to fill in the space created by a tab which ends at this custom tab stop. This character shall be repeated as required to completely fill the tab spacing generated by the tab character. If this attribute is omitted, then no tab leader character shall be used. [*Example*: Consider a tab stop which should be preceded by a sequence of underscore characters, as follows: _____Text at the tab stop This tab stop would have a leader attribute value of `underscore`, indicating that the tab stop shall be preceded by underscore characters as needed to fill the tab spacing. *end example*] The possible values for this attribute are defined by the ST_TabTlc simple type (§2.18.92).
pos (Tab Stop Position)	Specifies the position of the current custom tab stop with respect to the current page margins. Negative values are valid and move the tab stop into the current page margin the specified amount. [*Example*: Consider a custom tab stops at 1.5" in a WordprocessingML document. This tab stop would be contained within a tab element defining the tab stop as follows: `<w:tab w:val="left" w:pos="2160" />` The pos attribute specifies that this custom tab stop shall be located `2160` points (1.5 inches) inside the starting text margin. *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).
val (Tab Stop Type)	Specifies the type of custom tab stop, which determines the behavior of the tab stop and the alignment which shall be applied to text entered at the current custom tab stop. The value of `clear` is unique and specifies that this tab stop shall be removed when the document is next edited by a consumer which supports rendering the document

Attributes	Description
	contents. [*Example*: Consider a custom tab stops at 1.5" in a WordprocessingML document. This tab stop would be contained within a tab element defining the tab stop as follows: `<w:tab w:val="left" w:pos="2160" />` The val attribute specifies that this custom tab stop shall align all text entered at its location to its left. *end example*] The possible values for this attribute are defined by the ST_TabJc simple type (§2.18.91).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TabStop">
   <attribute name="val" type="ST_TabJc" use="required"/>
   <attribute name="leader" type="ST_TabTlc" use="optional"/>
   <attribute name="pos" type="ST_SignedTwipsMeasure" use="required"/>
</complexType>
```

2.3.1.38 tabs (Set of Custom Tab Stops)

This element specifies a sequence of custom tab stops which shall be used for any tab characters in the current paragraph.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no custom tab stops shall be used for this paragraph.

As well, this property is additive - tab stops at each level in the style hierarchy are added to each other to determine the full set of tab stops for the paragraph. A hanging indent specified via the hanging attribute on the ind element (§2.3.1.12) shall also always implicitly create a custom tab stop at its location.

[*Example*: Consider a paragraph which contains two custom tab stops at 1.5" and 3.5", respectively. These two tab stops would be contained within a tabs element defining the set of tab stops of the paragraph as follows:

```
<w:pPr>
  <w:tabs>
    <w:tab w:val="left" w:pos="2160" />
    <w:tab w:val="left" w:pos="5040" />
  </w:tabs>
</w:pPr>
```

The tabs element specifies all of the customized tab stops for the current paragraph. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Child Elements	Subclause
tab (Custom Tab Stop)	§2.3.1.37

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Tabs">
   <sequence>
      <element name="tab" type="CT_TabStop" minOccurs="1" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.3.1.39 textAlignment (Vertical Character Alignment on Line)

This element specifies the vertical alignment of all text on each line displayed within a paragraph. If the line height (before any added spacing) is larger than one or more characters on the line, all characters will be aligned to each other as specified by this element.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then the vertical alignment of all characters on the line shall be automatically determined by the consumer.

[*Example*: Consider a paragraph of text of different font sizes, as follows:

If the text on this paragraph shall be aligned based on the top point of the maximum character height, that requirement would be specified as follows in the WordprocessingML:

```
<w:pPr>
  <w:textAlignment w:val="top" />
</w:pPr>
```

The resulting text would be top aligned, as follows:

The characters are all aligned to the maximum character extent on the line. *end example*]

Parent Elements

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description

val (Vertical Character Alignment Position)	Specifies the type of vertical alignment which shall be used to align the characters on each line in the current paragraph.
	
	[*Example*: Consider a paragraph of text of different font sizes which shall be aligned based on the baseline point of each character in each line. This requirement would be specified as follows in the WordprocessingML:
	
	`<w:pPr>`
	`  <w:textAlignment w:val="baseLine" />`
	`</w:pPr>`
	
	The resulting text would be aligned to the baseline for each character on the line. *end example*]
	
	The possible values for this attribute are defined by the ST_TextAlignment simple type (§2.18.98).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TextAlignment">
   <attribute name="val" type="ST_TextAlignment" use="required"/>
</complexType>
```

2.3.1.40 textboxTightWrap (Allow Surrounding Paragraphs to Tight Wrap to Text Box Contents)

This element specifies whether, for paragraphs in a text box, the surrounding text shall be allowed to overlap with the empty text box boundaries and tight wrap to the extents of the text within the text box.

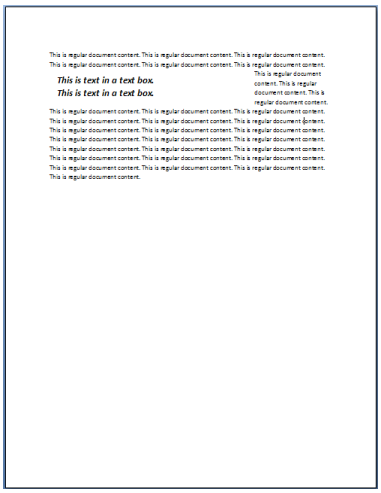
This element shall only be read for paragraphs which are contained within a text box (have a txbxContent ancestor), ignored otherwise.

If the parent text box does not meet the following three criteria, then this property has no effect:

- The text box wrapping must be set to `tight`
- The text box border must not be set
- The text box shading must not be set

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then paragraphs in a text box have no tight wrapping overrides, and text shall wrap to the extents of the text box.

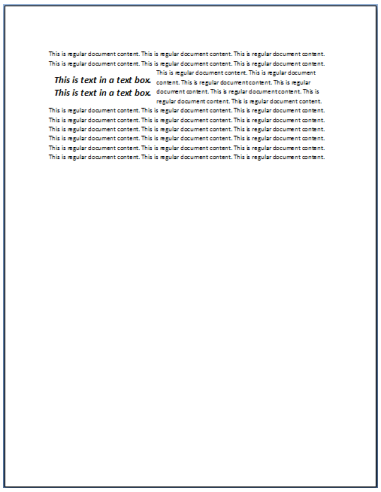
[*Example*: Consider a document with a tight wrapped text box which extends two-thirds of the way across the page, as follows:



The surrounding text is tightly wrapped to the extents of the text box. If the consumer shall tight wrap to the extents of the text, that requirement would be specified using the following WordprocessingML:

```
<w:pPr>
  <w:textboxTightWrap w:val="all" />
</w:pPr>
```

This would result in the following display of the content:



The resulting paragraphs within the textbox use the textboxTightWrap element to specify that text should be tightly wrapped to the paragraph's extents. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description

val (Lines to Tight Wrap to Paragraph Extents)	Specifies the lines in the parent paragraph which shall allow the text to be tight wrapped to the paragraph (and not the text box) extents when displaying the document.
	
	[*Example*: Consider a paragraph in a text box which meets the criteria specified above which shall allow wrapping to the text extents on its first line only. That requirement would be specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:textboxTightWrap w:val="firstLineOnly" />`
	`</w:pPr>`
	
	The resulting paragraph would allow text to tightly wrap to the contents of its first line only. All other lines would wrap to the text box's extents. *end example*]
	
	The possible values for this attribute are defined by the ST_TextboxTightWrap simple type (§2.18.99).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TextboxTightWrap">
   <attribute name="val" type="ST_TextboxTightWrap" use="required"/>
</complexType>
```

2.3.1.41 textDirection (Paragraph Text Flow Direction)

This element specifies the direction of the text flow for this paragraph.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then the paragraph shall inherit the text flow settings from the parent section.

[*Example*: Consider a document with a paragraph in which text should flow bottom to top vertically, and left to right horizontally. This setting would be specified with the following WordprocessingML:

```
<w:pPr>
  <w:textFlow w:val="btLr" />
</w:pPr>
```

The textFlow element specifies via the `btLr` value in the val attribute that the text flow should go bottom to top, and left to right. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description

Attributes	Description

val (Direction of Text Flow)	Specifies the direction of the text flow for this object.
	
	[*Example*: Consider a document with a section in which text shall flow bottom to top vertically, and left to right horizontally. This setting requires the following WordprocessingML:
	
	`<w:sectPr>`
	`…`
	`<w:textDirection w:val="btLr" />`
	`</w:sectPr>`
	
	The textDirection element specifies via the `btLr` value in the val attribute that the text flow shall go bottom to top, and left to right. *end example*]
	
	The possible values for this attribute are defined by the ST_TextDirection simple type (§2.18.100).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TextDirection">
   <attribute name="val" type="ST_TextDirection" use="required"/>
</complexType>
```

2.3.1.42 top (Paragraph Border Above Identical Paragraphs)

This element specifies the border which shall be displayed above a set of paragraphs which have the same set of paragraph border settings.

To determine if any two adjoining paragraphs shall have an individual top and bottom border or a between border, the set of borders on the two adjoining paragraphs are compared. If the border information on those two paragraphs is identical for all possible paragraphs borders, then the between border is displayed. Otherwise, the final paragraph shall use its bottom border and the following paragraph shall use its top border, respectively. If this border specifies a space attribute, that value determines the space above the text (ignoring any spacing above) which should be left before this border is drawn, specified in points.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then no between border shall be applied above identical paragraphs.

[*Example*: Consider the following two paragraphs' WordprocessingML definition:

```
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
```

```
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>First paragraph.</w:t>
  </w:r>
</w:p>
<w:p>
  <w:pPr>
    <w:pBdr>
      <w:top w:val="single" w:sz="24" w:space="1" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:left w:val="single" w:sz="24" w:space="4" w:color="B97034"
w:themeColor="accent6" w:themeShade="BF" />
      <w:bottom w:val="single" w:sz="24" w:space="0" w:color="F2DCDB"
w:themeColor="accent2" w:themeTint="33" />
      <w:right w:val="single" w:sz="24" w:space="4" w:color="C3D69B"
w:themeColor="accent3" w:themeTint="99" />
      <w:between w:val="single" w:sz="24" w:space="1" w:color="4F81BD"
w:themeColor="accent1" />
    </w:pBdr>
  </w:pPr>
  <w:r>
    <w:t>Second paragraph.</w:t>
  </w:r>
</w:p>
```

Since the paragraph border is different between the two paragraphs (the bottom space value goes from 1 to 0), paragraph two uses its top border, which is located one point above the text in that paragraph. *end example*]

Parent Elements
pBdr (§2.3.1.24)

Attributes	Description
color (Border Color)	Specifies the color for this border.

Attributes	Description
	This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is true, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />`

Attributes	Description
	This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`

Attributes	Description
	`<w:right w:val="dashed" w:sz="24" …/>` The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102$$

Attributes	Description
	$= 66(hex)$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}^{'} = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L^{'} = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated

Attributes	Description
	as follows: $$T_{xml} = 0.6 * 255 \\ = 153 \\ = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) \\ = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style.

Attributes	Description
	[*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.3.1.43 topLinePunct (Compress Punctuation at Start of a Line)

This element specifies whether punctuation shall be compressed when it appears as the first character in a line, allowing subsequent characters on the line to be move in accordingly.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then punctuation shall not be compressed in this paragraph, even when it appears at the start of a line.

[*Example*: Consider a paragraph which should allow punctuation at the start of a line to be compressed, in order to prevent it from taking up unnecessary space. This constraint is specified using the following WordprocessingML:

```
<w:pPr>
  <w:topLinePunct w:val="on" />
</w:pPr>
```

The topLinePunct element specifies that this compression shall be allowed when displaying this paragraph. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

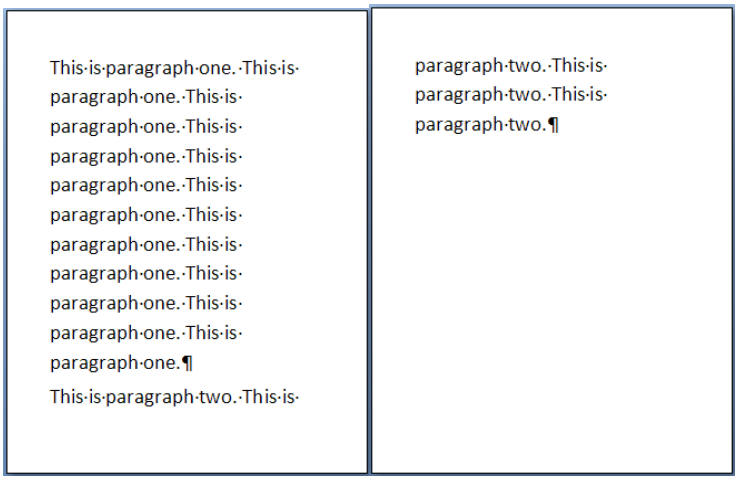
2.3.1.44 widowControl (Allow First/Last Line to Display on a Separate Page)

This element specifies whether a consumer shall prevent a single line of this paragraph from being displayed on a separate page from the remaining content at display time by moving the line onto the following page.

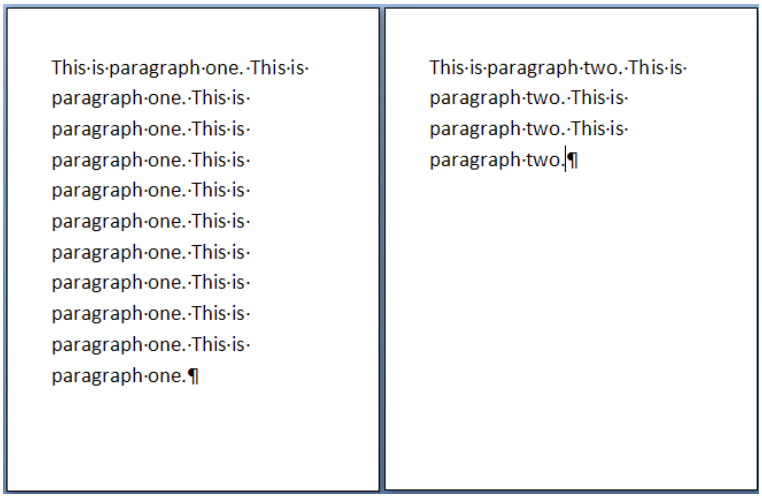
When displaying a paragraph in a page, it is sometimes the case that the first line of that paragraph would display as the last line on one page, and all subsequent lines would display on the following page. This property ensures that a consumer shall move the single line to the following page as well to prevent having one line on its own page. As well, if a single line appears at the top of a page, a consumer shall move the preceding line onto the following page as well, to prevent a single line from being displayed on a separate page.

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then this paragraph shall prevent a single line from being shown on a separate page whenever it would normally occur.

[*Example*: Consider a document with a paragraph which shall be shown on four lines at display time. If this paragraph would normally be laid out with its first line at the bottom of one page, and its following lines on the next page, as follows:



This property would ensure that the default behavior for each paragraph prevented this, by moving this line onto the following paragraph as follows:



However, if this default is overridden by specifying the following WordprocessingML:

```
<w:pPr>
  <w:widowControl w:val="off" />
</w:pPr>
```

The specifying of the widowControl element with value `off` means that the consumer displaying this document shall not move the first line onto a separate page if it would be separated from all other lines (the first picture above). *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.1.45 wordWrap (Allow Line Breaking At Character Level)

This element specifies whether a consumer shall break Latin text which exceeds the text extents of a line by breaking the word across two lines (breaking on the character level) or by moving the word to the following line (breaking on the word level).

If this element is omitted on a given paragraph, its value is determined by the setting previously set at any level of the style hierarchy (i.e. that previous setting remains unchanged). If this setting is never specified in the style hierarchy, then this paragraph shall break Latin words at the word level, not the character level when it is displayed.

[*Example*: Consider a paragraph whose first line ends with the word world, where the text extents for that line would normally fall between the letter o and the letter r. If this element is omitted, a producer would normally move the entire word world to the following line, since the word does not fit within the first line's text extents. However, if this document should allow words to be broken at the character level, that constraint would be specified as follows:

```
<w:pPr>
  <w:wordWrap w:val="off" />
</w:pPr>
```

The resulting paragraph specifies that wordWrap is turned off, therefore the word "world" would be broken into two lines between the exact two characters (o and r) that match the text extents. *end example*]

Parent Elements
pPr (§2.7.4.2); pPr (§2.9.24); pPr (§2.3.1.25); pPr (§2.7.5.1); pPr (§2.3.1.26); pPr (§2.7.7.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2 Run

The next level of the document hierarchy is the *run*, which defines a region of text with a common set of properties, represented by the r element (§2.3.2.23). An r element allows the producer to specify a single set of formatting properties, applying the same information to all the contents of the run.

Just as a paragraph can have properties, so too can a run. All of the elements inside an r element have their properties controlled by a corresponding optional rPr run properties element (§2.7.8.1; §2.3.2.26), which must be the first child of the r element. In turn, the rPr element is a container for a set of property elements that are applied to the rest of the children of the r element. [*Note*: The elements inside the rPr container element allow the consumer to control whether the content in the following run content is bold, underlined, or visible, for example. *end note*]

[*Example*: Consider the following run within a WordprocessingML document:

```
<w:r>
  <w:rPr>
    <w:b/>
    <w:i/>
  </w:rPr>
  <w:t>quick</w:t>
</w:r>
```

The run specifies two formatting properties in its run contents: bold and italic. These properties are therefore applied to all content within this run. *end example*]

2.3.2.1 b (Bold)

This element specifies whether the bold property shall be applied to all non-complex script characters in the contents of this run when displayed in a document.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to `false` (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then bold shall not be applied to non-complex script characters.

[*Example*: Consider a run of text which shall have the b property explicitly turned off for the non complex script contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:b w:val="false"/>
</w:rPr>
```

This run explicitly declares that the b property is `false` for the non-complex script contents of this run. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element.

Attributes	Description
	A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.2 bCs (Complex Script Bold)

This element specifies whether the bold property shall be applied to all complex script characters in the contents of this run when displayed in a document.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to false (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to true or false shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then bold shall not be applied to complex script characters.

[*Example*: Consider a run of text which shall have the bCs property (bold) explicitly turned on for the complex script contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:bCs w:val="true"/>
</w:rPr>
```

This run explicitly declares that the bCs property is true , so bold is turned on for the complex script contents of this run. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.3 bdr (Text Border)

This element specifies information about the border applied to the text in the current run.

The first piece of information specified by the bdr element is that the current shall have a border when displayed. This information is specified simply by the presence of the bdr element in run's properties.

The second piece of information concerns the set of runs which share the current run border. This is determined based on the attributes on the bdr element. If the set of attribute values specifies on two adjacent runs is identical, then those two runs shall be considered to be part of the same run border group and rendered within the same set of borders in the document.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then no run border shall be applied to the text in this run.

[*Example*: Consider a document in which the following two runs are located adjacent to one another:

```
<w:r>
  <w:rPr>
```

```
    <w:bdr w:val="single" w:sz="36" w:space="0" w:color="B8CCE4"
w:themeColor="accent1" w:themeTint="66" />
  </w:rPr>
  <w:t xml:space="preserve">run one</w:t>
</w:r>
<w:r >
  <w:rPr>
    <w:b />
    <w:bdr w:val="single" w:sz="36" w:space="0" w:color="B8CCE4"
w:themeColor="accent1" w:themeTint="66" />
  </w:rPr>
  <w:t>run two</w:t>
</w:r>
```

These two runs, although each is distinct, are combined when rendering the text border because the bdr elements are identical between the two runs. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text.

Attributes	Description
	If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`

Attributes	Description
	</w:pgBorders The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*] The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).
sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value. [*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup: <w:top w:val="dashed" w:sz="24" …/> <w:left w:val="dashed" w:sz="24" …/> <w:bottom w:val="dashed" w:sz="24" …/> <w:right w:val="dashed" w:sz="24" …/> The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).
themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup: <w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />

Attributes	Description

	`<w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	
	The borders have a color with an RGB value of `FFA8A0`, however, because the themeColor attribute is specified, that value is ignored in favor of the `accent2` theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be `66`. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `C0504D`. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$

Attributes	Description
	$= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $T_{xml} = 0.6 * 255$ $= 153$ $= 99(hex)$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD.

Attributes	Description
	The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L' = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.3.2.4 caps (Display All Characters As Capital Letters)

This element specifies that any lowercase characters in this text run shall be formatted for display only as their capital letter character equivalents. This property does not affect any non-alphabetic character in this run, and does not change the Unicode character for lowercase text, only the method in which it is displayed.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to `false` (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the characters are not formatted as capital letters.

This element shall not be present with the smallCaps (§2.3.2.31) property on the same run, since they are mutually exclusive in terms of appearance.

[*Example*: Consider the words `Hello World`, which shall be displayed in all capital letters in a document. This constraint is specified as follows in the WordprocessingML:

```
<w:r>
  <w:rPr>
    <w:caps w:val="true" />
  </w:rPr>
  <w:t>Hello World</w:t>
</w:r>
```

This run will display as `HELLO WORLD`, even though the lowercase characters are used in the run contents due to the use of the caps element. If this property is removed, the original character forms will be displayed (they are not lost). *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted.

Attributes	Description
	A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.5 color (Run Content Color)

This element specifies the color which shall be used to display the contents of this run in the document.

This color may be explicitly specified, or set to allow the consumer to automatically choose an appropriate color based on the background color behind the run's content.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the characters are set to allow the consumer to automatically choose an appropriate color based on the background color behind the run's content.

[*Example*: Consider a run of text which should be displayed using the `accent3` theme color from the document's Theme part. This requirement would be specified as follows in the resulting WordprocessingML:

```
<w:rPr>
  <w:color w:themeColor=”accent3” />
</w:rPr>
```

The color attribute specifies that the run shall use the `accent3` theme color. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
themeColor (Run Content Theme	Specifies a theme color which should be applied to the current run.

Attributes	Description

Color)	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows for color information to be set centrally in the document.
	
	If the themeColor attribute is specified, then the val attribute is ignored for this run.
	
	[*Example*: Consider a run of text which should be displayed using the accent3 theme color from the document's Theme part. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:color w:themeColor="accent3" />`
	`</w:rPr>`
	
	The color attribute specifies that the run shall use the accent3 theme color. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Run Content Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this run's contents. If the themeShade is supplied, then it is applied to the RGB value of the theme color to determine the final color applied to this run. The themeShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a run in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ Te resulting themeShade value in the file format would be 66. *end example*] Given a input red, green, or blue color value C (from 0-255), an output color value of C' (from 0-255), and a shade value S (from 0-100), the shade is applied as follows: $$C' = \left(1 - \frac{S}{100}\right) \mathrm{C}$$ [*Example*: Consider a document with a run using the accent6 theme color, whose RGB value (in RRGGBB hex format) is F79646.

Attributes	Description
	The hex value for the green component is 96 - 150 in decimal. Applying the shade formula with shade of 50%, the output decimal value of the green component is 75, or a hex value of 4B. This transformed value can be seen in the resulting run color WordprocessingML's val attribute: `<w:color w:val="7B4B23" w:themeColor="accent6" w:themeShade="80" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Run Content Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this run's contents. If the themeTint is supplied, then it is applied to the RGB value of the theme color to determine the final color applied to this run. The themeTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a run in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given a input red, green, or blue color value C (from 0-255), an output color value of C' (from 0-255), and a tint value T (from 0-100), the tint is applied as follows: $$C' = \left(1 - \frac{T}{100}\right)(255 - \mathrm{C}) + \mathrm{C}$$ [*Example*: Consider a document with a run using the accent1 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The hex value for the green component is 50 - 80 in decimal. Applying the tint formula with tint of 60%, the output decimal value of the green component is 150, or a hex value of 96. This transformed value can be seen in the resulting run color's WordprocessingML val attribute: `<w:color w:val="D99694" w:themeColor="accent1" w:themeTint="99" />`

Attributes	Description
	end example] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).

val (Run Content Color)	Specifies the color for this run.
	
	This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the run color as appropriate.
	
	If the run specifies the use of a theme color via the themeColor attribute, then this value is superseded by the theme color value.
	
	[*Example*: Consider a run color with value `auto`, as follows:
	
	`<w:rPr>`
	`  <w:color ... w:val="auto" />`
	`</w:rPr>`
	
	This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the run contents can be distinguished against the page's background color. *end example*]
	
	The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Color">
   <attribute name="val" type="ST_HexColor" use="required"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
</complexType>
```

2.3.2.6 cs (Use Complex Script Formatting on Run)

This element specifies whether the contents of this run shall be treated as complex script text regardless of their Unicode character values when determining the formatting for this run.

This means that a consumer shall use the complex script formatting applied to the run [*Example*: The bCs value (§2.3.2.2), not the b value (§2.3.2.1). *end example*] when determining the resulting formatting properties.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the run contents are set to complex script based on the Unicode character positions of the content.

[*Example*: Consider the following run of English text in a WordprocessingML document:

```
<w:r>
  <w:rPr>
    <w:bCs/>
    <w:i/>
    <w:cs/>
  </w:rPr>
  <w:t>some English text</w:t>
</w:r>
```

This run has bold applied to complex script characters, and italics applied to non-complex script characters. However, since the cs property is set, the text in this run shall be treated as complex script text when determining the resulting formatting. Therefore, the run will have bold formatting, but no italic formatting when displayed. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.7 dstrike (Double Strikethrough)

This element specifies that the contents of this run shall be displayed with two horizontal lines through each character displayed on the line.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then double strikethrough shall not be applied to the contents of this run.

This element shall not be present with the strike (§2.3.2.35) property on the same run, since they are mutually exclusive in terms of appearance.

[*Example*: Consider a run of text which shall have the dstrike property explicitly turned on for the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:dstrike w:val="true"/>
</w:rPr>
```

This run explicitly declares that the dstrike property is `true`, so the contents of this run will have two horizontal strikethrough lines. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.8 eastAsianLayout (East Asian Typography Settings)

This element specifies any East Asian typography settings which shall be applied to the contents of the run.

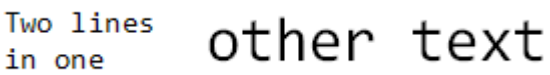
The specific typography settings represented by this element include the *two lines in one* and *horizontal in vertical* text options.

The *two lines in one* setting specifies that the characters in this run should be written out on a single line in the document by creating two sub-lines within the regular line, and laying out this text equally between those sub lines.

[*Example*: Consider a paragraph with the text `two lines in one`, which shall be displayed within a single logical line in the document. This constraint would be specified as follows in the WordprocessingML:

```
<w:r>
  <w:rPr>
    <w:eastAsianLayout w:id="1" w:combine="on" />
  </w:rPr>
  <w:t>two lines in one</w:t>
</w:r>
```

The resulting text would be displayed on two sub lines within the other text on this line, like this:



end example]

The *horizontal in vertical* setting specifies that characters in this run should be rendered with a 90 degree rotation to the left from all other contents of the line when displayed in the document, while keeping the text on the same line as all other text in the paragraph.

[*Example*: Consider a paragraph with the text `this word is vertical`, of which the word `vertical` shall be displayed vertically within the document. This constraint would be specified as follows in the WordprocessingML:

```
<w:r>
  <w:rPr>
    <w:eastAsianLayout w:id="2" w:vert="on" />
  </w:rPr>
  <w:t>vertical</w:t>
</w:r>
```

The resulting text would be displayed with a 90 degree rotation from the other text content. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

combine (Two Lines in One)	Specifies whether the contents of the current run should be combined into one line using the two lines in one logic described above in the parent element.
	
	If this attribute is omitted, then this run shall not be displayed on two sub lines.
	
	[*Example*: Consider a paragraph with the text `two lines in one`, which shall be displayed within a single logical line in the document. This constraint would be specified as follows in the WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:eastAsianLayout w:id="1" w:combine="on" />`
	`  </w:rPr>`
	`  <w:t>two lines in one</w:t>`
	`</w:r>`
	
	The resulting text would be displayed on two sub lines within the other text on this line. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

combineBrackets (Display Brackets Around Two Lines in One)	Specifies that the two lines in one text should be enclosed within a pair of brackets when displayed. This attribute's values determine the bracket style to put around combined text.
	
	If this attribute is not specified, then no brackets shall be placed around this content when displayed in the document. If the combine attribute is not specified, then this attribute is ignored.
	
	[*Example*: Consider a paragraph with the text `two lines in one`, which shall be displayed within a single logical line in the document and enclosed in curly brackets. This constraint would be specified as follows in the WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:eastAsianLayout w:id="1" w:combine="on"`
	`w:combineBrackets="curly"/>`
	`  </w:rPr>`
	`  <w:t>two lines in one</w:t>`
	`</w:r>`
	
	The resulting text would be displayed on two sub lines within the other text on this line and enclosed within curly brackets when displayed. *end example*]
	
	The possible values for this attribute are defined by the ST_CombineBrackets simple type (§2.18.13).

id (East Asian	Specifies a unique ID which shall b used to link multiple runs containing eastAsianLayout

Attributes	Description

Typography Run ID)	element to each other to ensure that their contents are correctly displayed in the document.
	
	This means that multiple runs which are broken apart due to differences in formatting can be identified as belonging to the same grouping in terms of eastAsianLayout properties, although they are separated into multiple runs of text.
	
	[*Example*: Consider the following three runs in a document:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:asianLayout w:id="-1552701694" w:combine="lines" w:combineBrackets="curly" />`
	`  </w:rPr>`
	`  <w:t>two</w:t>`
	`</w:r>`
	`<w:r>`
	`  <w:rPr>`
	`  <w:u w:val="single" w:color="4F81BD" w:themeColor="accent1" />`
	`  <w:asianLayout w:id="-1552701694" w:combine="lines" w:combineBrackets="curly" />`
	`  </w:rPr>`
	`  <w:t>lines in</w:t>`
	`</w:r>`
	`<w:r>`
	`  <w:rPr>`
	`  <w:asianLayout w:id="-1552701694" w:combine="lines" w:combineBrackets="curly" />`
	`  </w:rPr>`
	`  <w:t>one</w:t>`
	`</w:r>`
	
	Although there are three runs of content, all three regions shall be combined into a single two lines in one region based on the identical value used in the id attribute for all three runs. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

vert (Horizontal in Vertical (Rotate Text))	Specifies that characters in this run should be rendered with a 270 degree rotation to the left from all other contents of the line when displayed in the document as described above. If this attribute is omitted, then the contents of this run shall not be rotated with respect to the normal text flow. [*Example*: Consider a paragraph with the text `this word is vertical`, of which the

Attributes	Description

	word `vertical` shall be displayed vertically within the document. This constraint would be specified as follows in the WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:eastAsianLayout w:id="2" w:vert="on" />`
	`  </w:rPr>`
	`  <w:t>vertical</w:t>`
	`</w:r>`
	
	The resulting text would be displayed with a 270 degree rotation from the other text content. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

vertCompress (Compress Rotated Text to Line Height)	Specifies whether the rotated text shall be compressed at display time in order to ensure that it fits into the existing line height without increasing the overall height of the line.
	
	If the vert attribute is not specified, then this attribute is ignored. If this attribute is omitted, then text shall not be compressed in order to fit into the existing height of the line when it is rotated.
	
	[*Example*: Consider a paragraph with the text `this word is vertical`, of which the word `vertical` shall be displayed vertically within the document but shall not change the height of the line. This constraint would be specified as follows in the WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:eastAsianLayout w:id="2" w:vert="true"`
	`vertCompress="true" />`
	`  </w:rPr>`
	`  <w:t>vertical</w:t>`
	`</w:r>`
	
	The resulting text would be compressed in order to fit the height of the line as defined by all non-compressed characters. *end example*]
	
	The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_EastAsianLayout">
   <attribute name="id" type="ST_DecimalNumber" use="optional"/>
   <attribute name="combine" type="ST_OnOff" use="optional"/>
   <attribute name="combineBrackets" type="ST_CombineBrackets" use="optional"/>
   <attribute name="vert" type="ST_OnOff" use="optional"/>
   <attribute name="vertCompress" type="ST_OnOff" use="optional"/>
</complexType>
```

2.3.2.9 effect (Animated Text Effect)

This element specifies an animated text effect which should be displayed when rendering the contents of this run. This effect is rendered around the extents of the text in the run in the same location as a run border with zero pixels of padding would be rendered (if such a run border was present).

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then no text effect shall be applied to the contents of this run.

[*Example*: Consider a run of text which shall have an animated text effect consisting of multiple colored flashing lights (see possible attribute values for descriptions of each effect). This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:effect w:val="lights"/>
</w:rPr>
```

This run explicitly declares that the effect property is `lights`, so the contents of this run will have an animated lights text effect. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

val (Animated Text Effect Type)	Specifies the type of animated text effect which shall be applied to this text run.
	
	[*Example*: Consider a run of text which shall have an animated text effect consisting of multiple colored flashing lights. This constraint is specified using the following WordprocessingML:
	
	`<w:rPr>`
	`  <w:effect w:val="lights"/>`
	`</w:rPr>`
	
	This run explicitly declares a type of text effect, using the val property, of `lights`, so the contents of this run will have the animated lights text effect. *end example*]
	
	The possible values for this attribute are defined by the ST_TextEffect simple type (§2.18.101).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TextEffect">
   <attribute name="val" type="ST_TextEffect" use="required"/>
</complexType>
```

2.3.2.10 em (Emphasis Mark)

This element specifies the emphasis mark which shall be displayed for each non-space character in this run. An *emphasis mark* is an additional character that is rendered above or below the main character glyph as specified by the contents of the val attribute.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then no emphasis mark shall be added to each character in the contents of this run.

[*Example*: Consider a run of text which shall have a dot underneath each character as an emphasis mark. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:em w:val="dot"/>
</w:rPr>
```

This run explicitly declares that the emphasis mark type is dot, so the contents of this run will have a dot emphasis mark above each character. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

val (Emphasis Mark Type)	Specifies the emphasis mark type used for each character in this run.
	
	[*Example*: Consider a run of text which shall have a dot underneath each character as an emphasis mark. This constraint is specified using the following WordprocessingML:
	
	`<w:rPr>`
	`  <w:em w:val="dot"/>`
	`</w:rPr>`
	
	This run explicitly declares that the em type is dot, so the contents of this run will have a dot emphasis mark beneath each character. *end example*]
	
	The possible values for this attribute are defined by the ST_Em simple type (§2.18.28).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Em">
   <attribute name="val" type="ST_Em" use="required"/>
</complexType>
```

2.3.2.11 emboss (Embossing)

This element specifies that the contents of this run should be displayed as if embossed, which makes text appear as if it is raised off the page in relief.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to `false` (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then embossing shall not be applied to the contents of this run.

This element shall not be present with either the imprint (§2.3.2.16) or outline (§2.3.2.21) properties on the same run, since they are mutually exclusive in terms of appearance.

[*Example*: Consider a run of text which shall have the emboss property explicitly turned on for the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:emboss w:val="true"/>
</w:rPr>
```

This run explicitly declares that the emboss property is `true`, so the contents of this run will appear embossed. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted.

Attributes	Description
	A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.12 fitText (Manual Run Width)

This element specifies that the contents of this run shall not be automatically displayed based on the width of its contents, rather its contents shall be resized to fit the width specified by the val attribute. This expansion/contraction shall be performed by equally increasing/decreasing the size of each character in this run's contents when displayed.

If this element is omitted, then the contents of this run shall be displayed based on the size of its contents.

[*Example*: Consider a document with a run which shall be displayed in exactly one-half inch of space, regardless of its contents. This constraint would be specified using the following WordprocessingML:

```
<w:r>
  <w:rPr>
    <w:fitText w:id="50" w:val="720" />
  </w:rPr>
  <w:t>This text shall be displayed in one-half of an inch.</w:t>
</w:r>
```

The resulting run contents shall be displayed in exactly `720` twentieths of a point (one half of an inch) when displayed in a document. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
id (Fit Text Run ID)	Specifies a unique ID which shall be used to link multiple contiguous runs containing fitText elements to each other to ensure that their contents are correctly merged into

Attributes	Description

	the specified width in the document.
	
	This means that multiple runs which are broken apart due to differences in formatting can be identified as belonging to the same grouping in terms of fitText properties, although they are multiple runs of text in the WordprocessingML.
	
	If the runs are not contiguous, then the id attribute is ignored, and the runs are not linked.
	
	If this attribute is omitted, then this run has no id and shall not be linked with any other run in the parent paragraph.
	
	[*Example*: Consider the following three runs in a document, which should be fit into exactly one inch at display time:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:fitText w:id="99" w:val="1440" />`
	`  </w:rPr>`
	`  <w:t>fit this into</w:t>`
	`</w:r>`
	`<w:r>`
	`  <w:rPr>`
	`  <w:b/>`
	`  <w:fitText w:id="99" w:val="1440" />`
	`  </w:rPr>`
	`  <w:t>one</w:t>`
	`</w:r>`
	`<w:r>`
	`  <w:rPr>`
	`  <w:fitText w:id="99" w:val="1440" />`
	`  </w:rPr>`
	`  <w:t>inch</w:t>`
	`</w:r>`
	
	Although there are three runs of content, all three regions shall be combined into a single fit text region (e.g. they all fit into one inch, rather than one inch each) based on the identical value used in the id attribute for all three runs. *end example*]
	
	The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

val (Value)	This attribute specifies the exact width of space which this run shall be fit into when displayed in the document. [*Example*: Consider a document with a run which shall be displayed in exactly one-half inch of space, regardless of its contents. This constraint would be specified using the

Attributes	Description

	following WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:fitText w:id="50" w:val="720" />`
	`  </w:rPr>`
	`  <w:t>This text shall be displayed in one-half of an inch.</w:t>`
	`  </w:r>`
	
	The resulting run contents shall be displayed in exactly 720 twentieths of a point (one half of an inch) when displayed in a document. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_FitText">
   <attribute name="val" type="ST_TwipsMeasure" use="required"/>
   <attribute name="id" type="ST_DecimalNumber" use="optional"/>
</complexType>
```

2.3.2.13 highlight (Text Highlighting)

This element specifies a highlighting color which is applied as a background behind the contents of this run.

If this run has any background shading specified using the shd element (§2.3.2.30), then the background shading shall be superseded by the highlighting color when the contents of this run are displayed.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then text highlighting shall not be applied to the contents of this run.

[*Example*: Consider a run within a paragraph which has run shading applied as well as yellow text highlighting using the highlight element. This formatting is specified using the following WordprocessingML:

```
<w:rPr>
  <w:highlight w:val="yellow" />
  <w:shd w:themeFill="accent2" w:themeFillTint="66" />
</w:rPr>
```

The resulting run would have yellow highlighting visible over its contents, as the highlighting supersedes the shading for the contents of the run. *end example*]

Parent Elements

Parent Elements
rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

val (Highlighting Color)	Specifies the color of the text highlighting which shall be applied to the contents of this run.
	
	[*Example*: Consider a text run which shall be displayed with colored text highlighting. This highlighting would be specified using the following WordprocessingML:
	
	`<w:rPr>`
	`  <w:highlight w:val="red" />`
	`</w:rPr>`
	
	The resulting text highlighting would be `red`, as this is the color specified by the val attribute. *end example*]
	
	The possible values for this attribute are defined by the ST_HighlightColor simple type (§2.18.46).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Highlight">
   <attribute name="val" type="ST_HighlightColor" use="required"/>
</complexType>
```

2.3.2.14 i (Italics)

This element specifies whether the italic property should be applied to all non-complex script characters in the contents of this run when displayed in a document.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to `false` (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy* .If this element is never applied in the style hierarchy, then italics shall not be applied to non-complex script characters.

[*Example*: Consider a run of text which shall have the i property explicitly turned on for the non-complex script contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:i />
</w:rPr>
```

This run explicitly declares that the i property is `true` for the non-complex script contents of this run. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.15 iCs (Complex Script Italics)

This element specifies whether the italic property should be applied to all complex script characters in the contents of this run when displayed in a document.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to `false` (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then italics shall not be applied to complex script characters.

[*Example*: Consider a run of text which shall have the iCs property explicitly turned on for the complex script contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:iCs w:val="true"/>
</w:rPr>
```

This run explicitly declares that the iCs property is `true`, so italics are turned on for the complex script contents of this run. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
    <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.16 imprint (Imprinting)

This element specifies that the contents of this run should be displayed as if imprinted, which makes text appear to be imprinted or pressed into page (also referred to as 'engrave').

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to `false` (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then imprinting shall not be applied to the contents of this run.

This element shall not be present with either the emboss (§2.3.2.11) or outline (§2.3.2.21) properties on the same run, since they are mutually exclusive in terms of appearance.

[*Example*: Consider a run of text which shall have the imprint property explicitly turned on for the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:imprint w:val="true"/>
</w:rPr>
```

This run explicitly declares that the imprint property is `true`, so the contents of this run will appear imprinted. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.17 kern (Font Kerning)

This element specifies whether font kerning shall be applied to the contents of this run. If it is specified, then kerning shall be automatically adjusted when displaying characters in this run as needed.

The val attribute specifies the smallest font size which shall have its kerning automatically adjusted if this setting is specified. If the font size in the sz element (§2.3.2.36) is smaller than this value, then no font kerning shall be performed.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then font kerning shall not be applied to the contents of this run.

[*Example*: Consider the following WordprocessingML run which has font kerning properties specified:

```
<w:r>
  <w:rPr>
    <w:sz w:val="22" />
    <w:kern w:val="28" />
  </w:rPr>
</w:r>
```

Even though font kerning is turned on via the kern element, the contents of this run shall not be kerned because that settings only applied to font sizes of 14 points (28 half-points) or larger. If the kern element's val attribute was less than or equal to the sz element's val attribute, then kerning would be applied:

```
<w:r>
  <w:rPr>
    <w:sz w:val="22" />
    <w:kern w:val="22" />
  </w:rPr>
</w:r>
```

end example]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

Attributes	Description

val (Half Point Measurement)	Specifies a positive measurement specified in half-points (1/144 of an inch).
	
	The contents of this attribute value are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:rPr>`
	`  <w:sz w:val="28" />`
	`</w:rPr>`
	
	The value of the val attribute is the font size of the run's contents.
	
	However, consider the following fragment:
	
	`<w:rPr>`
	`  <w:kern w:val="30" />`
	`</w:rPr>`
	
	In this case, the value in the val attribute is the minimum size for which font characters shall be automatically kerned.
	
	In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_HpsMeasure simple type (§2.18.48).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HpsMeasure">
   <attribute name="val" type="ST_HpsMeasure" use="required"/>
</complexType>
```

2.3.2.18 lang (Languages for Run Content)

This element specifies the languages which shall be used to check spelling and grammar (if requested) when processing the contents of this run.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the languages for the contents of this run shall be automatically determined based on their contents using any method desired.

[*Example*: Consider a run which contains both Latin and complex script characters in its contents. If those contents should be interpreted as French (Canada) and Hebrew, respectively, that requirement would be specified as follows in the resulting WordprocessingML:

```
<w:r>
  <w:rPr>
```

```
      <w:lang w:val="fr-CA" w:bidi="he-IL" />
    </w:rPr>
  </w:r>
```

The resulting run specifies that any complex script contents shall be spell and grammar checked as if they were Hebrew, and any Latin character contents shall be spell and grammar checked as if they were French (Canada). *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

bidi (Complex Script Language)	Specifies the language which shall be used when processing the contents of this run which use complex script characters, as determined by the Unicode character values of the run content.
	
	If this attribute is omitted, then the languages for the contents of this run using complex script characters shall be automatically determined based on their contents using any appropriate method.
	
	[*Example*: Consider a run which contains complex script characters in its contents. If those contents should be interpreted as Hebrew, that requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:lang w:bidi="he-IL" />`
	`  </w:rPr>`
	`</w:r>`
	
	The resulting run specifies that any complex script contents shall be spell and grammar checked using a Hebrew dictionary and grammar engine, if one is available. *end example*]
	
	The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).

eastAsia (East Asian Language)	Specifies the language which shall be used when processing the contents of this run which use East Asian characters, as determined by the Unicode character values of the run content. If this attribute is omitted, then the languages for the contents of this run using East Asian characters shall be automatically determined based on their contents using any appropriate method. [*Example*: Consider a run which contains East Asian characters in its contents. If those contents should be interpreted as Korean, that requirement would be specified as

Attributes	Description

	follows in the resulting WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:lang w:bidi="ko-KR" />`
	`  </w:rPr>`
	`</w:r>`
	
	The resulting run specifies that any complex script contents shall be spell and grammar checked using a Korean dictionary and grammar engine, if one is available. *end example*]
	
	The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).

val (Latin Language)	Specifies the language which shall be used to check spelling and grammar (if requested) when processing the contents of this run which use Latin characters, as determined by the Unicode character values of the run content.
	
	If this attribute is omitted, then the languages for the contents of this run using Latin characters shall be automatically determined based on their contents using any appropriate method.
	
	[*Example*: Consider a run which contains Latin characters in its contents. If those contents should be interpreted as English (Canada), that requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:lang w:bidi="en-CA" />`
	`  </w:rPr>`
	`</w:r>`
	
	The resulting run specifies that any complex script contents shall be spell and grammar checked using a English (Canada) dictionary and grammar engine, if one is available. *end example*]
	
	The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Language">
   <attribute name="val" type="ST_Lang" use="optional"/>
   <attribute name="eastAsia" type="ST_Lang" use="optional"/>
   <attribute name="bidi" type="ST_Lang" use="optional"/>
</complexType>
```

2.3.2.19 noProof (Do Not Check Spelling or Grammar)

This element specifies that the contents of this run shall not report any errors when the document is scanned for spelling and grammar. [*Note*: It is entirely at the consumer's/producer's discretion whether this is done by not checking the region for spelling and grammar, or simply by suppressing the results. *end note*]

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then spelling and grammar error shall not be suppressed on the contents of this run.

[*Example*: Consider a run of text which shall not ever have spelling or grammar errors reported for the contents of the run, for example, the XML fragments included in this Specification. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:noProof w:val="true"/>
</w:rPr>
```

This run explicitly declares that the noProof property is `true`, so the contents of this run will never report spelling or grammar errors. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.20 oMath (Office Open XML Math)

This element specifies that this run contains WordprocessingML which shall be handled as though it was Office Open XML Math.

[*Rationale*: Like other run properties may be applied to the glyph representing the paragraph mark, it is possible to create an Office Open XML Math equation on an empty paragraph as well. Since that paragraph mark must be defined by WordprocessingML, it is not possible to store the paragraph using the Office Open XML Math markup. Instead, this run property is stored on the paragraph mark's run properties to indicate that the paragraph mark is part of an Office Open XML Math equation. For example, the first paragraph below is stored as Office Open XML Math:

The paragraph must be a p (§2.3.1.22) element, but that would mean the data loss of the Math markup when saving as a WordprocessingML package. In order to prevent that data loss, this property stores the Math property as a run property. *end rationale*]

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then this run shall not be treated as Office Open XML Math.

This property may be applied to any run, but that should only introduce the semantic that the run is math in the user interface, and shall not change the appearance of the text.

[*Example*: Consider a paragraph in WordprocessingML where the paragraph mark glyph (the pilcrow mark - ¶) has been formatted as Math. Since this mark is not an actual run, it cannot be written out in the Office Open XML Math syntax, and must be written out as a property on the actual run as follows:

```
<w:pPr>
  <w:rPr>
    <w:oMath />
  </w:rPr>
</w:pPr>
```

This property is therefore used to roundtrip the math setting on this paragraph mark character. *end example*]

Parent Elements

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.21 outline (Display Character Outline)

This element specifies that the contents of this run should be displayed as if they have an outline, by drawing a one pixel wide border around the inside and outside borders of each character glyph in the run.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to false (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to true or false shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then outline shall not be applied to the contents of this run.

This element shall not be present with either the emboss (§2.3.2.11) or imprint (§2.3.2.16) properties on the same run, since they are mutually exclusive in terms of appearance.

[*Example*: Consider a run of text which shall have the outline property explicitly turned off for the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:outline w:val="false"/>
</w:rPr>
```

This run explicitly declares that the outline property is `false`, so the contents of this run will not appear as if they have an exterior outline around them. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.22 position (Vertically Raised or Lowered Text)

This element specifies the amount by which text shall be raised or lowered for this run in relation to the default baseline of the surrounding non-positioned text. This allows the text to be repositioned without altering the font size of the contents.

If the val attribute is positive, then the parent run shall be raised above the baseline of the surrounding text by the specified number of half-points. If the val attribute is negative, then the parent run shall be lowered below the baseline of the surrounding text by the specified number of half-points.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the text shall not be raised or lowered relative to the default baseline location for the contents of this run.

[*Example*: Consider a run which shall be positioned 12 points above the default baseline location when displaying its contents. This requirement would be specified using the following WordprocessingML:

```
<w:rPr>
  <w:position w:val="24" />
</w:rPr>
```

The resulting run is positioned 24 half-points above the default baseline location because the contents of the val attribute are positive. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

val (Signed Half-Point Measurement)	Specifies a positive or negative measurement in half-points (1/144 of an inch).
	
	The contents of this attribute value are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:rPr>`
	`  <w:position w:val="-12" />`
	`</w:rPr>`
	
	In this case, the value in the val attribute is amount by which the specified run shall be raised or lowered compared to the baseline of the surrounding text.
	
	In all cases, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_SignedHpsMeasure simple type (§2.18.87).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SignedHpsMeasure">
   <attribute name="val" type="ST_SignedHpsMeasure" use="required"/>
</complexType>
```

2.3.2.23 r (Text Run)

This element specifies a run of content in the parent field, hyperlink, custom XML element, structured document tag, smart tag, or paragraph.

The contents of a run in a WordprocessingML document shall consist of any combination of run content.

[*Example*: Consider a basic WordprocessingML paragraph with a pair of runs. This run would be expressed as follows:

```
<w:document>
  <w:body>
    <w:p>
      <w:r>
        <w:t>Text</w:t>
      </w:r>
      <w:fldSimple w:instr="AUTHOR">
        <w:r>
          <w:t>Author Name</w:t>
        </w:r>
      </w:fldSimple>
    </w:p>
  </w:body>
</w:document>
```

The r element is the container for all of the content in the run, which in this example includes both a run in the paragraph and a run within a simple field. *end example*]

Parent Elements
customXml (§2.5.1.5); del (§2.13.5.12); fldSimple (§2.16.21); hyperlink (§2.16.24); ins (§2.13.5.20); moveFrom (§2.13.5.21); moveTo (§2.13.5.26); p (§2.3.1.22); rt (§2.3.3.23); rubyBase (§2.3.3.26); sdtContent (§2.5.2.35); smartTag (§2.5.1.9)

Attributes	Description
rsidDel (Revision Identifier for Run Deletion)	Specifies a unique identifier used to track the editing session when the run was deleted from the main document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications

Attributes	Description
	in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidR (Revision Identifier for Run)	Specifies a unique identifier used to track the editing session when the run was added to the main document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).
rsidRPr (Revision Identifier for Run Properties)	Specifies a unique identifier used to track the editing session when the run properties were last modified in the main document. All rsid* attributes throughout this document with the same value, if present, must indicate that those regions were modified during the same editing session (time between subsequent save actions). A producer may choose to increment the revision save ID value to indicate subsequent editing sessions to indicate the order of the modifications relative to other modifications in this document. The possible values for this attribute are defined by the ST_LongHexNumber simple type (§2.18.57).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_R">
   <sequence>
      <group ref="EG_RPr" minOccurs="0"/>
      <group ref="EG_RunInnerContent" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
   <attribute name="rsidRPr" type="ST_LongHexNumber"/>
   <attribute name="rsidDel" type="ST_LongHexNumber"/>
   <attribute name="rsidR" type="ST_LongHexNumber"/>
</complexType>
```

2.3.2.24 rFonts (Run Fonts)

This element specifies the fonts which shall be used to display the text contents of this run. Within a single run, there may be up to four types of content present which shall each be allowed to use a unique font:

- ASCII
- High ANSI
- Complex Script
- East Asian

The use of each of these fonts shall be determined by the Unicode character values of the run content, unless manually overridden via use of the cs element (§2.3.2.6).

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the text shall be displayed in any default font which supports each type of content.

[*Example*: Consider a single text run with both Arabic and English text, as follows:

English العربية

This content may be expressed in a single WordprocessingML run:

```
<w:r>
  <w:t>English العربية</w:t>
</w:r>
```

Although it is in the same run, the contents are in different font faces by specifying a different font for ASCII and CS characters in the run:

```
<w:r>
  <w:rPr>
    <w:rFonts w:ascii="Courier New" w:cs="Times New Roman" />
  </w:rPr>
  <w:t>English العربية</w:t>
</w:r>
```

This text run shall therefore use the Courier New font for all characters in the ASCII range, and shall use the Times New Roman font for all characters in the Complex Script range. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
ascii (ASCII Font)	Specifies a font which shall be used to format all characters in the ASCII range (0 - 127) within the parent run. If the asciiTheme attribute is also specified, then this attribute shall be ignored and that

Attributes	Description

	value shall be used instead.
	
	If this attribute is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this attribute is never applied in the style hierarchy, then the text shall be displayed in any default font which supports ASCII content.
	
	[*Example*: Consider a run of ASCII text which shall be displayed using the `Courier New` font. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:rFonts w:ascii=”Courier New” />`
	`</w:rPr>`
	
	The ascii attribute specifies that the run shall use the `Courier New` font for all text in the ASCII range. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

asciiTheme (ASCII Theme Font)	Specifies a theme font which shall be used to format all characters in the ASCII range (0 - 127) within the parent run. This theme font is a reference to one of the predefined theme fonts, located in the document's Theme part,which allows for font information to be set centrally in the document.
	
	If the ascii attribute is also specified, then that attribute shall be ignored and this value shall be used instead.
	
	If this attribute is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this attribute is never applied in the style hierarchy, then the text shall be displayed in the font specified by the ascii attribute.
	
	[*Example*: Consider a run of ASCII text which shall be displayed using the `majorASCII` theme font. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:rFonts w:asciiTheme=”majorAscii” />`
	`</w:rPr>`
	
	The ascii attribute specifies that the run shall use the `majorAscii` theme font as defined in the document's themes part for all text in the ASCII range. *end example*]
	
	The possible values for this attribute are defined by the ST_Theme simple type (§2.18.103).

cs (Complex Script Font)	Specifies a font which shall be used to format all characters in a complex script Unicode range within the parent run.

Attributes	Description

	If the csTheme attribute is also specified, then this attribute shall be ignored and that value shall be used instead.
	
	If this attribute is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this attribute is never applied in the style hierarchy, then the text shall be displayed in any default font which supports complex script content.
	
	[*Example*: Consider a run of Arabic text which shall be displayed using the `Arial Unicode MS` font. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:rFonts w:cs="Arial Unicode MS" />`
	`</w:rPr>`
	
	The cs attribute specifies that the run shall use the `Arial Unicode MS` font for all text in a complex script range. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

cstheme (Complex Script Theme Font)	Specifies a theme font which shall be used to format all characters in a complex script Unicode range within the parent run. This theme font is a reference to one of the predefined theme fonts, located in the document's Theme part,which allows for font information to be set centrally in the document.
	
	If the cs attribute is also specified, then that attribute shall be ignored and this value shall be used instead.
	
	If this attribute is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this attribute is never applied in the style hierarchy, then the text shall be displayed in the font specified by the cs attribute.
	
	[*Example*: Consider a run of Arabic text which shall be displayed using the `majorBidi` theme font. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:rFonts w:csTheme="majorBidi" />`
	`</w:rPr>`
	
	The csTheme attribute specifies that the run shall use the `majorBidi` theme font as defined in the document's themes part for all text in a complex script range. *end example*]
	
	The possible values for this attribute are defined by the ST_Theme simple type (§2.18.103).

Attributes	Description

eastAsia (East Asian Font)	Specifies a font which shall be used to format all characters in an East Asian Unicode range within the parent run.
	
	If the eastAsiaTheme attribute is also specified, then this attribute shall be ignored and that value shall be used instead.
	
	If this attribute is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this attribute is never applied in the style hierarchy, then the text shall be displayed in any default font which supports East Asian content.
	
	[*Example*: Consider a run of Japanese text which shall be displayed using the `MS Mincho` font. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:rFonts w:eastAsia=”MS Mincho” />`
	`</w:rPr>`
	
	The eastAsia attribute specifies that the run shall use the `MS Mincho` font for all text in an East Asian range. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

eastAsiaTheme (East Asian Theme Font)	Specifies a theme font which shall be used to format all characters in an East Asian Unicode range within the parent run. This theme font is a reference to one of the predefined theme fonts, located in the document's Theme part,which allows for font information to be set centrally in the document.
	
	If the eastAsia attribute is also specified, then that attribute shall be ignored and this value shall be used instead.
	
	If this attribute is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this attribute is never applied in the style hierarchy, then the text shall be displayed in the font specified by the eastAsia attribute.
	
	[*Example*: Consider a run of Japanese text which shall be displayed using the `minorEastAsia` theme font. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:rFonts w:eastAsiaTheme=”minorEastAsia” />`
	`</w:rPr>`
	
	The eastAsiaTheme attribute specifies that the run shall use the `minorEastAsia` theme font as defined in the document's themes part for all text in an East Asian range. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_Theme simple type (§2.18.103).

hAnsi (High ANSI Font)	Specifies a font which shall be used to format all characters in a Unicode range within the parent run which does not fall into one of the three categories defined above, which is called the *high ANSI* range in WordprocessingML.
	
	If the hAnsiTheme attribute is also specified, then this attribute shall be ignored and that value shall be used instead.
	
	If this attribute is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this attribute is never applied in the style hierarchy, then the text shall be displayed in any default font which supports high ANSI content.
	
	[*Example*: Consider a run of text which falls into a high ANSI range, and shall be displayed using the `Bauhaus 93` font. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:rFonts w:hAnsi=”Bauhaus 93” />`
	`</w:rPr>`
	
	The hAnsi attribute specifies that the run shall use the `Bauhaus 93` font for all text in a high ANSI range. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

hAnsiTheme (High ANSI Theme Font)	Specifies a theme font which shall be used to format all characters in a Unicode range within the parent run which does not fall into one of the three categories defined above, which is called the *high ANSI* range in WordprocessingML. This theme font is a reference to one of the predefined theme fonts, located in the document's Theme part,which allows for font information to be set centrally in the document.
	
	If the hAnsi attribute is also specified, then that attribute shall be ignored and this value shall be used instead.
	
	If this attribute is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this attribute is never applied in the style hierarchy, then the text shall be displayed in the font specified by the hAnsi attribute.
	
	[*Example*: Consider a run of text which falls into a high ANSI range, and shall be displayed using the `minorHAnsi` theme font. This requirement would be specified as follows in the resulting WordprocessingML:
	
	`<w:rPr>`
	`  <w:rFonts w:hAnsiTheme="minorHAnsi" />`
	`</w:rPr>`

Attributes	Description
	The hAnsiTheme attribute specifies that the run shall use the `minorHAnsi` theme font as defined in the document's themes part for all text in a high ANSI range. *end example*] The possible values for this attribute are defined by the ST_Theme simple type (§2.18.103).

hint (Font Content Type)	Specifies the font type which shall be used to format any ambiguous characters in the current run.
	
	There are certain characters which are not explicitly stored in the document, and may be mapped into multiple categories of the four mentioned above. This attribute shall be used to arbitrate that conflict, and determine how ambiguities in this run shall be handled. [*Note*: This is primarily used to handle the formatting on the paragraph mark glyph, and other characters that are not stored as text in the WordprocessingML document. *end note*]
	
	If this attribute is omitted, then this ambiguity may be resolved by any means available.
	
	[*Example*: Consider the run representing the paragraph mark glyph, which is not stored as a physical character. Since this could therefore be formatted with any of the fonts specified for the run, this ambiguity is resolved using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:rPr>`
	`  <w:rFonts w:hint="eastAsia" />`
	`  </w:rPr>`
	`</w:pPr>`
	
	The hint attribute specifies that the run shall use the `eastAsia` font (theme or not, whichever is in use for East Asian text) as defined for this range. *end example*]
	
	The possible values for this attribute are defined by the ST_Hint simple type (§2.18.47).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Fonts">
   <attribute name="hint" type="ST_Hint"/>
   <attribute name="ascii" type="ST_String"/>
   <attribute name="hAnsi" type="ST_String"/>
   <attribute name="eastAsia" type="ST_String"/>
   <attribute name="cs" type="ST_String"/>
   <attribute name="asciiTheme" type="ST_Theme"/>
   <attribute name="hAnsiTheme" type="ST_Theme"/>
   <attribute name="eastAsiaTheme" type="ST_Theme"/>
   <attribute name="cstheme" type="ST_Theme"/>
</complexType>
```

2.3.2.25 rPr (Run Properties)

This element specifies a set of run properties which shall be applied to the contents of the parent run after all style formatting has been applied to the text. These properties are defined as *direct formatting*, since they are directly applied to the run and supersede any formatting from styles.

This formatting is applied at the following location in the *style hierarchy*:

- Document defaults
- Table styles
- Numbering styles
- Paragraph styles
- Character styles
- Direct formatting (this element)

[*Example*: Consider a run which should have a set of run formatting properties. This set of properties is specified in the run properties as follows:

```
<w:r>
  <w:rPr>
    <w:b />
    <w:imprint />
    <w:lang w:val="en-ca" />
  </w:rPr>
</w:r>
```

The rPr element specifies the properties which are applied to the current run - in this case, bold formatting on the run contents using the b element (§2.3.2.1), an imprinted (engraved) text effect using the imprint element (§2.3.2.16), and that this text should be interpreted as English (Canada) when spell or grammar checking the run text using the lang element (§2.3.2.18). *end example*]

Parent Elements
ctrlPr (§7.1.2.23); r (§7.1.2.87); r (§2.3.2.23)

strike (Single Strikethrough)	§2.3.2.35
sz (Font Size)	§2.3.2.36
szCs (Complex Script Font Size)	§2.3.2.37
u (Underline)	§2.3.2.38
vanish (Hidden Text)	§2.3.2.39
vertAlign (Subscript/Superscript Text)	§2.3.2.40
w (Expanded/Compressed Text)	§2.3.2.41
webHidden (Web Hidden Text)	§2.3.2.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPr">
   <sequence>
      <group ref="EG_RPrContent" minOccurs="0"/>
   </sequence>
</complexType>
```

2.3.2.26 rPr (Previous Run Properties)

This element specifies a set of run properties which shall be attributed to a revision by a particular author and at a particular time. This element contains the set of properties which have been tracked as a specific set of revisions by one author.

[*Example*: Consider a run which has a set of run formatting properties that were added with revision tracking turned on. This set of revised properties is specified in the run properties as follows:

```
<w:r>
  <w:rPr>
    <w:b />
    <w:imprint />
    <w:lang w:val="en-ca" />
    <w:rPrChange w:author="user1">
      <w:rPr>
        <w:i />
        <w:dstrike w:val="false" />
      </w:rPr>
    </w:rPrChange>
  </w:rPr>
</w:r>
```

The rPr element under rPrChange specifies the properties which were applied to the current run before revision tracking was turned on - in this case, italics using the i element (§2.3.2.14), and that any double strikethrough which was applied based on the style hierarchy shall be turned off using the dstrike element (§2.3.2.7). *end example*]

vertAlign (Subscript/Superscript Text)	§2.3.2.40
w (Expanded/Compressed Text)	§2.3.2.41

Child Elements	Subclause
webHidden (Web Hidden Text)	§2.3.2.42

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RPrOriginal">
   <sequence>
      <group ref="EG_RPrBase" minOccurs="0" maxOccurs="unbounded"/>
   </sequence>
</complexType>
```

2.3.2.27 rStyle (Referenced Character Style)

This element specifies the style ID of the character style which shall be used to format the contents of this paragraph.

This formatting is applied at the following location in the *style hierarchy*:

- Document defaults
- Table styles
- Numbering styles
- Paragraph styles
- Character styles (this element)
- Direct Formatting

This means that all properties specified in the style element (§2.7.3.17) with a styleId which corresponds to the value in this element's val attribute are applied to the run at the appropriate level in the hierarchy.

If this element is omitted, or it references a style which does not exist, then no character style shall be applied to the current paragraph. As well, this property is ignored if the run properties are part of a character style.

[*Example*: Consider the following WordprocessingML fragment:

```
<w:rPr>
  <w:pStyle w:val=”TestCharacterStyle” />
  <w:b />
  <w:i />
</w:rPr>
```

This run specifies that it will inherit all of the run properties specified by the paragraph style with a styleId of `TestCharacterStyle`, which will then have any bold or italics settings overridden and set to be applied to the run. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

val (String Value)	Specifies that its contents will contain a string.
	
	The contents of this string are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:pPr>`
	`  <w:pStyle w:val="heading1" />`
	`</w:pPr>`
	
	The value of the val attribute is the ID of the associated paragraph style's `styleId`.
	
	However, consider the following fragment:
	
	`<w:sdtPr>`
	`  <w:alias w:val="SDT Title Example" />`
	`  ...`
	`</w:sdtPr>`
	
	In this case, the decimal number in the val attribute is the caption of the parent structured document tag. In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_String">
   <attribute name="val" type="ST_String" use="required"/>
</complexType>
```

2.3.2.28 rtl (Right To Left Text)

This element specifies that the alignment and reading order for this run shall be right to left. This setting determines the way in which the run contents are presented in the document when punctuation characters are part of the run's contents. When this property is specified, each part of the run between a punctuation mark shall be laid out right to left on the line.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then right to left alignment shall not be applied to the contents of this run.

[*Example*: Consider the following run of English text: `This is a list: one, two, three.` Typically, each region of text between a punctuation mark is presented in a left to right reading order in the document (as shown above). If the right to left property is set on this text, as follows:

```
<w:rPr>
  <w:rtl v:val="on"/>
</w:rPr>
```

This run shall now have a right to left reading order, as follows:

```
.three ,two ,one :This is a list
```

In a right to left language, this would result in the correct placement of the punctuation with respect to each region of right to left text. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.29 shadow (Shadow)

This element specifies that the contents of this run shall be displayed as if each character has a shadow, displayed beneath the text and to its right.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to false (or an equivalent) shall result in the current setting remaining

unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then shadowing shall not be applied to the contents of this run.

This element shall not be present with either the emboss (§2.3.2.11) or imprint (§2.3.2.16) properties on the same run, since they are mutually exclusive in terms of appearance.

[*Example*: Consider a run of text which shall have the shadow property explicitly turned on for the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:shadow w:val="true"/>
</w:rPr>
```

This run explicitly declares that the shadow property is `true`, so the contents of this run will appear with a shadow. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.30 shd (Run Shading)

Like paragraph shading, this element specifies the shading applied to the contents of the run.

This shading consists of three components:

- Background Color
- (optional) Pattern
- (optional) Pattern Color

The resulting shading is applied by setting the background color behind the paragraph, then applying the pattern color using the mask supplied by the pattern over that background.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then run shading shall not be applied to the contents of this run.

[*Example*: Consider a run which shall have a background consisting of a theme color `accent6` with a theme color `text2` overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:

```
<w:pPr>
  <w:shd w:val="pct20" w:themeColor="text2" w:themeFill="accent6" />
</w:pPr>
```

The resulting run will use the background color `accent6` under the foreground pattern color `text2` as specified by the `pct20` pattern mask. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
color (Shading Pattern Color)	Specifies the color used for any foreground pattern specified for this shading using the val attribute. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the foreground shading color as appropriate. If the shading style (the val attribute) specifies the use of no shading format or is omitted, then this property has no effect. Also, if the shading specifies the use of a theme color via the themeColor attribute, then this value is superseded by the theme color value. If this attribute is omitted, then its value shall be assumed to be `auto`.

Attributes	Description
	[*Example*: Consider a shading of type `pct20` with a foreground color value of `auto`, as follows: `<w:shd w:val="pct20"... w:color="auto"/>` The foreground color for this shading pattern therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the shading color can be distinguished against the page's background color. *end example*] The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
fill (Shading Background Color)	Specifies the color used for the background for this shading. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the background shading color as appropriate. If this attribute is omitted, then its value shall be assumed to be `auto`. [*Example*: Consider a shading using a background color of hex value C3D69B, using the following WordprocessingML: `<w:shd w:fill="C3D69B" />` The background color for this shading therefore will be a color with a hex value of `C3D69B`. *end example*] If the shading specifies the use of a theme color via the themeFill attribute, then this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
themeColor (Shading Pattern Theme Color)	Specifies a theme color which should be applied to any foreground pattern specified for this shading using the val attribute. The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document. If this element is omitted, then no theme color is applied, and the color attribute shall be used to determine the shading pattern color. [*Example*: Consider a paragraph which shall have a background consisting of a theme color `accent3` with a theme color `accent6` overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:

Attributes	Description
	<w:pPr> <w:shd w:val="pct20" w:themeColor="accent6" w:themeFill="accent3" /> </w:pPr> The resulting paragraph will use the foreground pattern color accent6 in the region specified by the pct20 pattern mask. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeFill (Shading Background Theme Color)	Specifies a theme color which should be applied to the background for this shading. The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document. If this element is omitted, then no theme color is applied, and the color attribute shall be used to determine the shading background color. [*Example*: Consider a paragraph which shall have a background consisting of a theme color accent3 with a theme color accent6 overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML: <w:shd w:val="pct20" w:themeColor="accent6" w:themeFill="accent3" /> The resulting shading will use the background color specified by the accent3 theme color. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeFillShade (Shading Background Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this shading color. If the themeFillShade is supplied, then it is applied to the RGB value of the themeFill color (from the theme part) to determine the final color applied to this border. The themeFillShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $S_{xml} = 0.4 * 255$ $= 102$ $= 66(hex)$

Attributes	Description
	The resulting themeFillShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * Shade_{percentage}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting shading's fill attribute: `<w:shd w:fill="943634" w:themeFill="accent2" w:themeFillShade="BF" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeFillTint (Shading Background Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeFillTint is supplied, then it is applied to the RGB value of the themeFill color (from the theme part) to determine the final color applied to this border. The themeFillTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows:

Attributes	Description
	$$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeFillTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting shading's fill attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:fill="95B3D7" w:themeFillColor="accent2" w:themeFillTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeShade (Shading Pattern Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this shading color. If the themeShade is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border.

Attributes	Description
	[*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ Te resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}^{'} = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L^{'} = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:shd w:color="943634" w:themeColor="accent2" w:themeShade="BF" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Shading Pattern Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeTint is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border.

Attributes	Description
	The themeTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 \\ = 153 \\ = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) \\ = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting shading's color attribute: `<w:shd w:color="95B3D7" w:themeColor="accent2" w:themeTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Shading Pattern)	Specifies the pattern which shall be used to lay the pattern color over the background color for this paragraph shading.

Attributes	Description
	This pattern consists of a mask which is applied over the background shading color to get the locations where the pattern color should be shown. Each of these possible masks are shown in the simple type values referenced below. [*Example*: Consider a shaded paragraph which uses a 10 percent foreground fill, resulting in the following WordprocessingML: `<w:shd w:val="pct10" .../>` This shading val is `pct10`, indicating that the border style is a 10 percent foreground fill mask. *end example*] The possible values for this attribute are defined by the ST_Shd simple type (§2.18.85).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Shd">
   <attribute name="val" type="ST_Shd" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="fill" type="ST_HexColor" use="optional"/>
   <attribute name="themeFill" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeFillTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeFillShade" type="ST_UcharHexNumber" use="optional"/>
</complexType>
```

2.3.2.31 smallCaps (Small Caps)

This element specifies that all small letter characters in this text run shall be formatted for display only as their capital letter character equivalents in a font size two points smaller than the actual font size specified for this text. This property does not affect any non-alphabetic character in this run, and does not change the Unicode character for lowercase text, only the method in which it is displayed. If this font cannot be made two point smaller than the current size, then it shall be displayed as the smallest possible font size in capital letters.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to `false` (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the characters are not formatted as capital letters.

This element shall not be present with the caps (§2.3.2.4) property on the same run, since they are mutually exclusive in terms of appearance.

[*Example*: Consider the words `Hello World`, which shall be displayed in small capital letters in a document. This constraint is specified as follows in the WordprocessingML:

```
<w:r>
  <w:rPr>
    <w:sz w:val="24" />
    <w:smallCaps w:val="true" />
  </w:rPr>
  <w:t>Hello World</w:t>
</w:r>
```

This run will display using a 12 point capital letter for the capital letter H and W, and a 10 point capital letter for the lowercase letters in the run, even though the lowercase characters are used in actual run contents. If this property is removed, the original character forms will be displayed (they are not lost). *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.32 snapToGrid (Use Document Grid Settings For Inter-Character Spacing)

This element specifies whether the current run should use the document grid characters per line settings defined in the docGrid element (§2.6.5) when laying out the contents in this run. This setting determines whether the additional character pitch specified in the document grid shall be added to each character in this run as specified by the document grid.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the run shall use the document grid setting to lay out text when a document grid is defined for the parent section.

[*Example*: Consider two runs in a section with a document grid set to allow 20 characters per line. This document grid would effectively specifies that an additional character pitch shall be added to each line in order to ensure that the resulting line contains only 20 East Asian characters.

If this property is set on the first run, but turned off on the second run, as follows:

```
<w:r>
  <w:t>Run One</w:t>
</w:r>
<w:r>
  <w:rPr>
    <w:snapToGrid w:val="off" />
  </w:rPr>
  <w:t>Run Two</w:t>
</w:r>
```

The resulting document shall have the required additional character pitch added to each character in run one, but zero additional character pitch added to each character in run two, since the snapToGrid property is turned off. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off.

Attributes	Description
	[*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.33 spacing (Character Spacing Adjustment)

This element specifies the amount of character pitch which shall be added or removed after each character in this run before the following character is rendered in the document. This property has an effect equivalent to the additional character pitched added by a document grid applied to the contents of a run.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the run shall not have any additional character pitch applied to any character in its contents.

[*Example*: Consider a run of text which shall have ten points of additional character spacing explicitly added to each character within the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:spacing w:val="200"/>
</w:rPr>
```

This run explicitly declares that the spacing value is 200, so the contents of this run will appear as if they have 10 additional points of spacing added between them. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (Positive or Negative Value in Twentieths of a Point)	Specifies a value whose contents shall contain a positive whole number, whose contents consist of a positive or negative measurement in twentieths of a point (equivalent to 1/1440th of an inch). The contents of this measurement shall be interpreted based on the context of the

Attributes	Description
	parent XML element. [*Example*: Consider an attribute value of `-720` whose type is ST_SignedTwipsMeasure. This attribute value specifies a value of negative one-half of an inch or -36 points (`-720` twentieths of a point = -36 points = -0.5 inches). *end example*] The possible values for this attribute are defined by the ST_SignedTwipsMeasure simple type (§2.18.88).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_SignedTwipsMeasure">
    <attribute name="val" type="ST_SignedTwipsMeasure" use="required"/>
</complexType>
```

2.3.2.34 specVanish (Paragraph Mark Is Always Hidden)

This element specifies that the given run shall always behave as if it is hidden, even when hidden text is being displayed in the current document.

This property shall only be used to specify that a paragraph mark shall never be used to break the end of a paragraph for display, even if it is being shown on the document, as would be the case if a regularly hidden paragraph was not being displayed in the document. [*Note*: This property was typically used to ensure that a paragraph style can be applied to a part of a paragraph, and still appear as in the Table of Contents (which in previous word processors would ignore the use of the style if it were being used as a character style. *end note*] If this element is applied to any other run, it may be ignored.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the run properties for the paragraph mark shall not always be treated as if hidden.

[*Example*: Consider a paragraph mark which never be used to break the end of the paragraph in the document. This constraint is specified using the following WordprocessingML:

```
<w:pPr>
  <w:rPr>
    <w:specVanish />
  </w:rPr>
</w:pPr>
```

The presence of the specVanish element means that this paragraph mark shall always be treated as hidden (shall never be used to end the paragraph for display), but may be used to mark the end of use of a paragraph style. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30);

Parent Elements
rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.35 strike (Single Strikethrough)

This element specifies that the contents of this run shall be displayed with a single horizontal line through the center of the line.

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to `false` (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then strikethrough shall not be applied to the contents of this run.

This element shall not be present with the dstrike (§2.3.2.7) property on the same run, since they are mutually exclusive in terms of appearance.

[*Example*: Consider a run of text which shall have the strike property explicitly turned on for the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:strike w:val="true"/>
</w:rPr>
```

This run explicitly declares that the strike property is `true`, so the contents of this run will have a single horizontal strikethrough line. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.36 sz (Font Size)

This element specifies the font size which shall be applied to all non complex script characters in the contents of this run when displayed.

If this element is not present, the default value is to leave the value applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then any appropriate font size may be used for non complex script characters.

[*Example*: Consider a run of text which shall have an explicit font size of 13.5 points for the non complex script contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:sz w:val="27"/>
</w:rPr>
```

This run explicitly declares that the sz property is 27 half-point for the non-complex script contents of this run, so the text will be displayed in 13.5 point font size. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

val (Half Point Measurement)	Specifies a positive measurement specified in half-points (1/144 of an inch).
	
	The contents of this attribute value are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:rPr>`
	`  <w:sz w:val="28" />`
	`</w:rPr>`
	
	The value of the val attribute is the font size of the run's contents.
	
	However, consider the following fragment:
	
	`<w:rPr>`
	`  <w:kern w:val="30" />`
	`</w:rPr>`
	
	In this case, the value in the val attribute is the minimum size for which font characters shall be automatically kerned.
	
	In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_HpsMeasure simple type (§2.18.48).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HpsMeasure">
   <attribute name="val" type="ST_HpsMeasure" use="required"/>
</complexType>
```

2.3.2.37 szCs (Complex Script Font Size)

This element specifies the font size which shall be applied to all complex script characters in the contents of this run when displayed.

If this element is not present, the default value is to leave the value applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then any appropriate font size may be used for complex script characters.

[*Example*: Consider a run of text which shall have an explicit font size of 10 points for the complex script contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:szCs w:val="20"/>
</w:rPr>
```

This run explicitly declares that the sz property is 20 half-point for the non-complex script contents of this run, so the text will be displayed in 10 point font size. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

val (Half Point Measurement)	Specifies a positive measurement specified in half-points (1/144 of an inch).
	
	The contents of this attribute value are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:rPr>`
	`  <w:sz w:val="28" />`
	`</w:rPr>`
	
	The value of the val attribute is the font size of the run's contents.
	
	However, consider the following fragment:
	
	`<w:rPr>`
	`  <w:kern w:val="30" />`
	`</w:rPr>`
	
	In this case, the value in the val attribute is the minimum size for which font characters shall be automatically kerned.

Attributes	Description
	In each case, the value is interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_HpsMeasure simple type (§2.18.48).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HpsMeasure">
   <attribute name="val" type="ST_HpsMeasure" use="required"/>
</complexType>
```

2.3.2.38 u (Underline)

This element specifies that the contents of this run should be displayed along with an underline appearing directly below the character height (less all spacing above and below the characters on the line).

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then an underline shall not be applied to the contents of this run.

[*Example*: Consider a run of text which shall have a double underline explicitly turned on for the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:u w:val="double"/>
</w:rPr>
```

This run explicitly declares an underline using the u property. The val of that underline is `double`, so the style of the underline on this run shall be a double line. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
color (Underline Color)	Specifies the color for the underlining on this run. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the underline color as appropriate. If the underline specifies the use of a theme color via the themeColor attribute, then this value is superseded by the theme color value. [*Example*: Consider a run color with value `auto`, as follows:

Attributes	Description
	<w:rPr> <w:un … w:color="auto" /> </w:rPr> This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the underline can be distinguished against the page's background color. *end example*] The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
themeColor (Underline Theme Color)	Specifies a theme color which should be applied to the current underline. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows for color information to be set centrally in the document. If the themeColor attribute is specified, then the color attribute is ignored for this underline. [*Example*: Consider an underlined run of text whose underline should be displayed using the accent3 theme color from the document's Theme part. This requirement would be specified as follows in the resulting WordprocessingML: <w:rPr> <w:u … w:themeColor="accent3" /> </w:rPr> The themeColor attribute specifies that the underline shall use the accent3 theme color. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Underline Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this underline. If the themeShade is supplied, then it is applied to the RGB value of the theme color to determine the final color applied to this underline. The themeShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a underline in a document. This shade is calculated as follows: $S_{xml} = 0.4 * 255$ $= 102$ $= 66(hex)$

Attributes	Description
	The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * Shade_{percentage}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting underline's color attribute: `<w:u w:color="943634" w:themeColor="accent2" w:themeShade="BF" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Underline Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this underline's contents. If the themeTint is supplied, then it is applied to the RGB value of the theme color to determine the final color applied to this run. The themeTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to an underline in a document. This tint is calculated as follows:

Attributes	Description
	$$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting underline formatting's WordprocessingML color attribute: `<w:u … w:color="95B3D7" w:themeColor="accent2" w:themeTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Underline Style)	Specifies the pattern which shall be used to create the underline applied beneath the text in this run. Each of these possible patterns are shown in the simple type referenced below. [*Example*: Consider a run of text which shall have a double underline explicitly turned on for the contents of the run. This constraint is specified using the following WordprocessingML:

Attributes	Description
	<w:rPr> <w:u w:val="double"/> </w:rPr> The val of the underline on this run is double, so the style of the underline on this run shall be a double line. *end example*] The possible values for this attribute are defined by the ST_Underline simple type (§2.18.107).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Underline">
   <attribute name="val" type="ST_Underline" use="optional"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
</complexType>
```

2.3.2.39 vanish (Hidden Text)

This element specifies whether the contents of this run shall be hidden from display at display time in a document. [*Note*: The setting should affect the normal display of text, but an application may have settings to force hidden text to be displayed. *end note*]

This formatting property is a *toggle property*, which specifies that its behavior differs between its use within a style definition and its use as direct formatting. When used as part of a style definition, setting this property shall toggle the current state of that property as specified up to this point in the hierarchy (i.e. applied to not applied, and vice versa). Setting it to `false` (or an equivalent) shall result in the current setting remaining unchanged. However, when used as direct formatting, setting this property to `true` or `false` shall set the absolute state of the resulting property.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy* .If this element is never applied in the style hierarchy, then this text shall not be hidden when displayed in a document.

[*Example*: Consider a run of text which shall have the hidden text property turned on for the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:vanish />
</w:rPr>
```

This run declares that the vanish property is set for the contents of this run, so the contents of this run will be hidden when the document contents are displayed. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.2.40 vertAlign (Subscript/Superscript Text)

This element specifies the alignment which shall be applied to the contents of this run in relation to the default appearance of the run's text. This allows the text to be repositioned as subscript or superscript without altering the font size of the run properties.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the text shall not be subscript or superscript relative to the default baseline location for the contents of this run.

[*Example*: Consider a run which shall be positioning as superscript when displaying its contents. This requirement would be specified using the following WordprocessingML:

```
<w:rPr>
  <w:vertAlign w:val="superscript" />
</w:rPr>
```

The resulting run is positioned as superscript, therefore it is rendered in a smaller size above the default baseline location for the contents of the run. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

val (Subscript/Superscript Value)	Specifies the type of vertical alignment applied to the contents of the current run.
	
	[*Example*: Consider a run which shall be positioning as superscript when displaying its contents. This requirement would be specified using the following WordprocessingML:
	
	`<w:rPr>`
	`  <w:vertAlign w:val="superscript" />`
	`</w:rPr>`
	
	The value of the val attribute is `superscript`, therefore the run's contents are rendered in a smaller size above the default baseline location for the contents of the run. *end example*]
	
	The possible values for this attribute are defined by the ST_VerticalAlignRun simple type (§2.18.110).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_VerticalAlignRun">
   <attribute name="val" type="ST_VerticalAlignRun" use="required"/>
</complexType>
```

2.3.2.41 w (Expanded/Compressed Text)

This element specifies the amount by which each character shall be expanded or when the character is rendered in the document. This property has an of stretching or compressing each character in the run, as opposed to the spacing element (§2.3.2.33) which expands/compresses the text by adding additional character pitch but not changing the width of the actual characters displayed on the line.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy*. If this element is never applied in the style hierarchy, then the run shall be displayed at 100% of its normal width.

[*Example*: Consider a run of text which shall be expanded to 200% of its normal width when displaying each character within the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:w w:val="200"/>
</w:rPr>
```

This run explicitly declares that the w value is 200, so the contents of this run will appear at 200% of their normal character width by stretching the width of each character. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description

val (Text Expansion/Compression Value)	Specifies that the percentage by which the contents of this run shall be expanded or compressed with respect to its normal (100%) character width.
	
	If this attribute is omitted, then the contents of this run shall be displayed at 100% of its normal size.
	
	[*Example*: Consider a run of text which shall be compressed to 200% when displaying each character within the contents of the run. This constraint is specified using the following WordprocessingML:
	
	`<w:rPr>`
	`  <w:w w:val="50"/>`
	`</w:rPr>`
	
	This run explicitly declares that the w value is 50, so the contents of this run will appear at 50% of their normal character width by compressing the width of each character. *end example*]
	
	The possible values for this attribute are defined by the ST_TextScale simple type (§2.18.102).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TextScale">
   <attribute name="val" type="ST_TextScale"/>
</complexType>
```

2.3.2.42 webHidden (Web Hidden Text)

This element specifies whether the contents of this run shall be hidden from display at display time in a document when the document is being displayed in a web page view. [*Note*: The setting should affect the normal display of text in a web page view, but an application may have settings to force hidden text to be displayed. *end note*] As well, this setting should not affect a normal paginated view of the document.

If this element is not present, the default value is to leave the formatting applied at previous level in the *style hierarchy* .If this element is never applied in the style hierarchy, then this text shall not be hidden when displayed in a document in a web page view.

[*Example*: Consider a run of text which shall have the hidden text property turned on for the contents of the run. This constraint is specified using the following WordprocessingML:

```
<w:rPr>
  <w:webHidden />
</w:rPr>
```

This run declares that the webHidden property is set for the contents of this run, so the contents of this run will be hidden when the document contents are displayed in a web page view. *end example*]

Parent Elements
rPr (§2.7.8.1); rPr (§2.3.1.29); rPr (§2.5.2.26); rPr (§2.3.2.25); rPr (§2.3.2.26); rPr (§2.7.4.4); rPr (§2.3.1.30); rPr (§2.9.26); rPr (§2.5.2.27); rPr (§2.7.5.2)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.3 Run Content

The final level of the document hierarchy is *run content*, which is defined as the set of elements which can be contained as the contents of a particular run in a document.

[*Note*: Types of run content in WordprocessingML include:

- Text
- Field Codes
- DrawingML objects

- VML objects
- Fields

end note]

[*Example*: Consider the following run within a WordprocessingML document:

```
<w:r>
  <w:rPr>
    <w:b/>
    <w:i/>
  </w:rPr>
  <w:t>quick</w:t>
</w:r>
```

The run content consists of a single string of run text inside the t element, which reads `quick`. *end example*]

2.3.3.1 br (Break)

This element specifies that a break shall be placed at the current location in the run content. A *break* is a special character which is used to override the normal line breaking that would be performed based on the normal layout of the document's contents. [*Example*: Normal breaking for English would occur only after a breaking space or optional hyphen character. *end example*]

The behavior of this break character (the location where text shall be restarted after this break) shall be determined by its type and clear attribute values, described below.

[*Example*: Consider the following sentence in a WordprocessingML document:

```
This is a simple sentence.
```

Normally, just as shown above, this sentence would be displayed on a single line as it is not long enough to require line breaking (given the width of the current page). However, if a text wrapping break character (a typical line break) were inserted after the word `is`, as follows:

```
<w:r>
  <w:t>This is</w:t>
  <w:br/>
  <w:t xml:space="preserve"> a simple sentence.</w:t>
</w:r>
```

This would imply that this break shall be treated as a simple line break, and break the line after that word:

```
This is
 a simple sentence.
```

The break character forced the following text to be restarted on the next available line in the document. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Attributes	Description
clear (Restart Location For Text Wrapping Break)	Specifies the location which shall be used as the next available line when the break's type attribute has a value of `textWrapping`. This property only affects the restart location when the current run is being displayed on a line which does not span the full text extents due to the presence of a floating object (see possible values for details). If this break is not of type `textWrapping`, then this attribute shall be ignored. If this attribute is omitted, then its value shall be assumed to be none if needed. [*Example*: Consider a text wrapping break character which should force the restart location to the next line which spans the full width of the text extents of the page (there are no floating objects which interrupt the line). This line break is of type `textWrapping`, since it shall only advance to the next line, but the clear value shall specify that this restart location shall ignore all lines which are not of the full line width by specifying a value of `all`, as follows: `<w:br w:type="textWrapping" w:clear="all" />` This break shall therefore not use the next available line, but rather the next available line ignoring all lines which do not span the full text width. *end example*] The possible values for this attribute are defined by the ST_BrClear simple type (§2.18.5).
type (Break Type)	Specifies the type of the current break. The break type determines the next location where text shall be placed after this manual break is applied to the text contents (see possible values for details). If this attribute is omitted, then it shall be assumed to be of type `textWrapping`. [*Example*: Consider a manual break which shall advance the text to the next text column in the document, rather than just the next available line. This break would therefore be specified as follows: `<w:br w:type=”column”/>` The type attribute specifies a value of `column`, which means that the break shall force the next character in the document to be restarted on the next line in a new text column in the document. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_BrType simple type (§2.18.6).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Br">
   <attribute name="type" type="ST_BrType" use="optional"/>
   <attribute name="clear" type="ST_BrClear" use="optional"/>
</complexType>
```

2.3.3.2 control (Floating Embedded Control)

This element specifies that the parent VML object is a representation of an embedded control at the current location in the document. This element shall be used to associate the VML data with the appropriate embedded control settings and properties when the document is displayed.

If the embedded control is not present, cannot be loaded due to application settings, or is not supported, then the VML data shall be used to provide an image representation of the control at the appropriate location in the document.

[*Example*: Consider a run which consists of an embedded control. That run would be specified using the following WordprocessingML:

```
<w:r>
  <w:pict>
    …
    <w:control r:id=”rId99” w:shapeid=”shape01” … />
  </w:pict>
</w:r>
```

The control element indicates that the parent VML object contains the positioning and last known image representation of an embedded control, whose settings and properties are stored on this element. *end example*]

Parent Elements
pict (§2.3.3.21); pict (§2.9.23)

Attributes	Description
id (Embedded Control Properties Relationship Reference) Namespace: …/officeDocument/2006/relationshi	Specifies the relationship ID for the relationship which contains the properties for this embedded control. This property bag is contained in a separate part within the Word Open XML package. The relationship explicitly targeted by this attribute shall be of type http://schemas.openxmlformats.org/officeDocument/2006/relationships/control or the document shall be conisdered non-conformant.

Attributes	Description
ps	If this attribute is omitted, then the embedded control shall be given no property bag when instantiated. [*Example*: Consider the following WordprocessingML markup for an embedded control in a document: `<w:control r:id="rId5" w:id="CheckBox1" w:name="CheckBox1" w:shapeid="_x0000_s1027" w:class="shape" w:w="145" w:h="28" w:align="left" />` The id attribute in the relationship reference namespace specifies that the relationship with relationship ID `rId5` shall contain the property data for this embedded control. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).
name (Unique Name for Embedded Control)	Specifies a unique name for this embedded control. This name shall be unique across all controls in this document. [*Example*: Consider the following WordprocessingML markup for an embedded control in a document: `<w:control r:id="rId5" w:id="CheckBox1" w:name="CheckBox1" w:shapeid="_x0000_s1027" w:class="shape" w:w="145" w:h="28" w:align="left" />` The name attribute specifies that the unique name for this control shall be `CheckBox1`. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
shapeid (Associated VML Data Reference)	Specifies the shape ID for a shape which shall be used to define the presentation and location of this embedded control within the document if the control is floating using the VML syntax. [*Note*: This positioning data is sufficient to display the control in any case where: • The embedded control is not on the current machine • Embedded controls are disabled • Embedded controls of this type are not supported *end note*] This shape ID reference is resolved by looking for a VML shape element (§6.1.2.19) whose id attribute matches the value specified within this attribute. If no such shape exists, then the control shall be rendered inline in the document content at the current run content location.

Attributes	Description
	If this attribute is omitted, then this embedded control shall be displayed inline in the current location in the parent run. [*Example*: Consider the following WordprocessingML markup for an embedded control in a document: `<w:control r:id="rId5" w:id="CheckBox1" w:name="CheckBox1" w:shapeid="_x0000_s1027" w:class="shape" w:w="145" w:h="28" w:align="left" />` The shapeid attribute specifies that the VML shape element with a shape id attribute value of `_x0000_s1027` shall contain the VML positioning data for this embedded control. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Control">
   <attribute name="name" type="ST_String" use="optional"/>
   <attribute name="shapeid" type="ST_String" use="optional"/>
   <attribute ref="r:id" use="optional"/>
</complexType>
```

2.3.3.3 control (Inline Embedded Control)

This element specifies that the parent embedded object is a representation of an embedded control at the current location in the document. This element shall be used to associate the appropriate embedded control settings and properties when the document is displayed.

If the embedded control is not present, cannot be loaded due to application settings, or is not supported, then a suitable placeholder image shall be used to provide a representation of the presence of an embedded control at the appropriate location in the document.

[*Example*: Consider a run which consists of an embedded control. That run would be specified using the following WordprocessingML:

```
<w:r>
  <w:object>
    …
    <w:control r:id=”rId99” w:shapeid=”shape01” … />
  </w:object>
</w:r>
```

The control element indicates that the parent embedded object is an embedded control, whose settings and properties are stored on this element and the (optional) target of the relationship specified using the id attribute. *end example*]

Parent Elements
object (§2.3.3.19)

Attributes	Description
id (Embedded Control Properties Relationship Reference) Namespace: .../officeDocument/2006/relationships	Specifies the relationship ID for the relationship which contains the properties for this embedded control. This property bag is contained in a separate part within the Word Open XML package. The relationship explicitly targeted by this attribute shall be of type http://schemas.openxmlformats.org/officeDocument/2006/relationships/control or the document shall be conisdered non-conformant. If this attribute is omitted, then the embedded control shall be given no property bag when instantiated. [*Example*: Consider the following WordprocessingML markup for an embedded control in a document: `<w:control r:id="rId5" w:id="CheckBox1" w:name="CheckBox1" w:shapeid="_x0000_s1027" w:class="shape" w:w="145" w:h="28" w:align="left" />` The id attribute in the relationship reference namespace specifies that the relationship with relationship ID `rId5` shall contain the property data for this embedded control. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).
name (Unique Name for Embedded Control)	Specifies a unique name for this embedded control. This name shall be unique across all controls in this document. [*Example*: Consider the following WordprocessingML markup for an embedded control in a document: `<w:control r:id="rId5" w:id="CheckBox1" w:name="CheckBox1" w:shapeid="_x0000_s1027" w:class="shape" w:w="145" w:h="28" w:align="left" />` The name attribute specifies that the unique name for this control shall be `CheckBox1`. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).
shapeid (Associated VML Data Reference)	Specifies the shape ID for a shape which shall be used to define the presentation and location of this embedded control within the document if the control is floating using the VML syntax.

Attributes	Description
	[*Note*: This positioning data is sufficient to display the control in any case where: • The embedded control is not on the current machine • Embedded controls are disabled • Embedded controls of this type are not supported *end note*] This shape ID reference is resolved by looking for a VML shape element (§6.1.2.19) whose id attribute matches the value specified within this attribute. If no such shape exists, then the control shall be rendered inline in the document content at the current run content location. If this attribute is omitted, then this embedded control shall be displayed inline in the current location in the parent run. [*Example*: Consider the following WordprocessingML markup for an embedded control in a document: `<w:control r:id="rId5" w:id="CheckBox1" w:name="CheckBox1" w:shapeid="_x0000_s1027" w:class="shape" w:w="145" w:h="28" w:align="left" />` The shapeid attribute specifies that the VML shape element with a shape id attribute value of `_x0000_s1027` shall contain the VML positioning data for this embedded control. *end example*] The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Control">
   <attribute name="name" type="ST_String" use="optional"/>
   <attribute name="shapeid" type="ST_String" use="optional"/>
   <attribute ref="r:id" use="optional"/>
</complexType>
```

2.3.3.4 cr (Carriage Return)

This element specifies that a carriage return shall be placed at the current location in the run content. A *carriage return* is the equivalent of Unicode character 000D, and is used to end the current line of text in WordprocessingML.

The behavior of a carriage return in run content shall be identical to a break character with null type and clear attributes, which shall end the current line and find the next available line on which to continue.

[*Example*: Consider the following sentence in a WordprocessingML document:

```
This is another simple sentence.
```

Normally, just as shown above, this sentence would be displayed on a single line as it is not long enough to require line breaking (given the width of the current page). However, if a carriage return were inserted after the word another, as follows:

```
<w:r>
  <w:t>This is another</w:t>
  <w:cr/>
  <w:t xml:space="preserve"> simple sentence.</w:t>
</w:r>
```

This would imply that this carriage return character shall force a line break, and break the line after that word:

```
This is another
 simple sentence.
```

The carriage return character forced the following text to be restarted on the next available line in the document. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.5 dayLong (Date Block - Long Day Format)

This element specifies the presence of a date block at the current location in the run content. A *date block* is a non-editable region of text which shall display the current date filtered through the specified date picture (see following paragraphs) . [*Note*: The date block is a legacy construct used for compatibility with older word processors, and should not be produced unless it was consumed while reading a document – it is recommended that the DATE field is used in its place. *end note*]

A date block shall be displayed using the primary editing language of the host application, regardless of the languages specified in the parent run's lang property (§2.3.2.18).

The long day format date block shall use a date picture of DDDD, retrieving the long day format for the primary editing language.

[*Example*: Consider a WordprocessingML run with the following run content:

```
<w:r>
  <w:t xml:space="preserve">This is a long date: </w:t>
  <w:dayLong />
</w:r>
```

This run specifies that a long day format date block shall be placed after the text string literal `This is a long date:` in the document. Assuming that the host application's primary editing language is French (Canada) and today's date is 04/12/2006 (a Wednesday), this run would be displayed as follows:

```
This is a long date: mercredi
```

end example]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.6 dayShort (Date Block - Short Day Format)

This element specifies the presence of a date block at the current location in the run content. A *date block* is a non-editable region of text which shall display the current date filtered through the specified date picture (see following paragraphs) . [*Note*: The date block is a legacy construct used for compatibility with older word processors, and should not be produced unless it was consumed while reading a document – it is recommended that the DATE field is used in its place. *end note*]

A date block shall be displayed using the primary editing language of the host application, regardless of the languages specified in the parent run's lang property (§2.3.2.18).

The short day format date block shall use a date picture of DD, retrieving the short day format for the primary editing language.

[*Example*: Consider a WordprocessingML run with the following run content:

```
<w:r>
  <w:t xml:space="preserve">This is a short date: </w:t>
  <w:dayShort />
</w:r>
```

This run specifies that a short day format date block shall be placed after the text string literal `This is a short date:` in the document. Assuming that the host application's primary editing language is English (Canada) and today's date is 04/12/2006 (a Wednesday), this run would be displayed as follows:

```
This is a short date: 12
```

end example]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.7 delText (Deleted Text)

This element specifies that this run contains literal text which shall be displayed in the document. The `delText` element shall be used for all text runs which are part of a region of text that is contained in a deleted region using the del element (§2.13.5.12).

[*Example*: Consider a paragraph of WordprocessingML content which reads `This is deleted text`, where the words `deleted text` are part of a deleted region of the document. This paragraph would therefore be represented as follows:

```
<w:p>
  <w:r>
    <w:t xml:space="preserve">This is </w:t>
  </w:r>
  <w:del>
    <w:r>
      <w:delText>deleted text</w:delText>
    </w:r>
  </w:del>
</w:p>
```

The deleted text is contained in a delText node, while the regular text is contained in a t node. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Attributes	Description

space (Content Contains Significant Whitespace)
 	
Namespace: http://www.w3.org/XML/1998/namespace
	Specifies how white space should be handled for the contents of this element using the W3C space preservation rules.
	
	[*Example*: Consider the following run contained within a WordprocessingML document:
	
	`<w:r>`
	`  <w:t>significant whitespace  </w:t>`
	`</w:r>`
	
	Although there are three spaces on each side of the text content in the run, that whitespace has not been specifically marked as significant, therefore it is removed when this run is added to the document. *end example*]
	
	The possible values for this attribute are defined by the type in the namespace.

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Text">
   <simpleContent>
      <extension base="ST_String">
         <attribute ref="xml:space" use="optional"/>
      </extension>
   </simpleContent>
</complexType>
```

2.3.3.8 dirty (Invalidated Field Cache)

This element specifies that the field has been changed and the results shall be updated on open in a conforming consumer.

Parent Elements
rubyPr (§2.3.3.27)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: <w:… w:val="off"/> The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.3.3.9 drawing (DrawingML Object)

This element specifies that a DrawingML object is located at this position in the run's contents. The layout properties of this DrawingML object are specified using the WordprocessingML Drawing syntax (§5.5).

[*Example*: Consider a run which consists of a picture which is in line with the text in that paragraph (i.e. on the line and affects the line height). That run would be specified using the following WordprocessingML:

```
<w:r>
  <w:drawing>
    <wp:inline>
      …
    </wp:inline>
  </w:drawing>
</w:r>
```

The drawing element indicates that a DrawingML object and its WordprocessingML Drawing positioning data are located at the current position in the run (e.g. a picture or a chart). *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Child Elements	Subclause
anchor (Anchor for Floating DrawingML Object)	§5.5.2.3
inline (Inline DrawingML Object)	§5.5.2.8

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Drawing">
   <choice minOccurs="1" maxOccurs="unbounded">
      <element ref="wp:anchor" minOccurs="0"/>
      <element ref="wp:inline" minOccurs="0"/>
   </choice>
</complexType>
```

2.3.3.10 hps (Phonetic Guide Text Font Size)

This element specifies the font size which shall be applied to the phonetic guide text in the contents of this run when displayed.

If this element disagrees with the run properties on the phonetic guide text rt element (§2.3.3.23), then those properties shall be ignored and this element shall determine the size of the phonetic guide text.

[*Example*: Consider a run of phonetic guide text which shall have an explicit font size of 13.5 points. This constraint is specified using the following WordprocessingML:

```
<w:rubyPr>
  …
  <w:hps w:val="27"/>
  …
</w:rubyPr>
```

The hps property is 27 half-points for the ruby text in this run, so the phonetic guide text will be displayed in 13.5 point font size. *end example*]

Parent Elements
rubyPr (§2.3.3.27)

Attributes	Description

val (Half Point Measurement)	Specifies a positive measurement specified in half-points (1/144 of an inch).
	
	The contents of this attribute value are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:rPr>`
	`  <w:sz w:val="28" />`
	`</w:rPr>`
	
	The value of the val attribute is the font size of the run's contents.
	
	However, consider the following fragment:
	
	`<w:rPr>`
	`  <w:kern w:val="30" />`
	`</w:rPr>`
	
	In this case, the value in the val attribute is the minimum size for which font characters shall be automatically kerned.
	
	In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_HpsMeasure simple type (§2.18.48).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HpsMeasure">
   <attribute name="val" type="ST_HpsMeasure" use="required"/>
</complexType>
```

2.3.3.11 hpsBaseText (Phonetic Guide Base Text Font Size)

This element specifies the font size which shall be applied to the base text of this phonetic guide text when displayed. If this element disagrees with the run properties on the phonetic guide base text rubyBase element (§2.3.3.26), then this property shall be ignored and the sz element (§2.3.2.36) in that run shall determine the size of the phonetic guide base text.

[*Example*: Consider a run of phonetic guide base text which shall have an explicit font size of 30 points. This constraint is specified using the following WordprocessingML:

```
<w:rubyPr>
  …
  <w:hpsBaseText w:val="60"/>
  …
</w:rubyPr>
```

The hpsBaseText property is 60 half-points for the base text in this phonetic guide, so the phonetic guide base text will be displayed in 30 point font size. *end example*]

Parent Elements
rubyPr (§2.3.3.27)

Attributes	Description

val (Half Point Measurement)	Specifies a positive measurement specified in half-points (1/144 of an inch).
	
	The contents of this attribute value are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:rPr>`
	`  <w:sz w:val="28" />`
	`</w:rPr>`
	
	The value of the val attribute is the font size of the run's contents.
	
	However, consider the following fragment:
	
	`<w:rPr>`
	`  <w:kern w:val="30" />`
	`</w:rPr>`
	
	In this case, the value in the val attribute is the minimum size for which font characters shall be automatically kerned.
	
	In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_HpsMeasure simple type (§2.18.48).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HpsMeasure">
    <attribute name="val" type="ST_HpsMeasure" use="required"/>
</complexType>
```

2.3.3.12 hpsRaise (Distance Between Phonetic Guide Text and Phonetic Guide Base Text)

This element specifies the distance which shall be left between the phonetic guide base text and the phonetic guide text when this phonetic guide text is displayed.

[*Example*: Consider a run of phonetic guide text which shall have 10 points between the phonetic guide base text and the phonetic guide text. This constraint is specified using the following WordprocessingML:

```
<w:rubyPr>
  …
  <w:hpsRaise w:val="20"/>
  …
</w:rubyPr>
```

The hpsRaise property is 20 half-points for the phonetic guide, so the phonetic guide text will be displayed 10 points above the phonetic guide base text. *end example*]

Parent Elements
rubyPr (§2.3.3.27)

Attributes	Description

val (Half Point Measurement)	Specifies a positive measurement specified in half-points (1/144 of an inch).
	
	The contents of this attribute value are interpreted based on the context of the parent XML element.
	
	[*Example*: Consider the following WordprocessingML fragment:
	
	`<w:rPr>`
	`  <w:sz w:val="28" />`
	`</w:rPr>`
	
	The value of the val attribute is the font size of the run's contents.
	
	However, consider the following fragment:
	
	`<w:rPr>`
	`  <w:kern w:val="30" />`
	`</w:rPr>`
	
	In this case, the value in the val attribute is the minimum size for which font characters shall be automatically kerned.
	
	In each case, the value is interpreted in the context of the parent element. *end example*]
	
	The possible values for this attribute are defined by the ST_HpsMeasure simple type

Attributes	Description
	(§2.18.48).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HpsMeasure">
   <attribute name="val" type="ST_HpsMeasure" use="required"/>
</complexType>
```

2.3.3.13 lastRenderedPageBreak (Position of Last Calculated Page Break)

This element specifies that this position delimited the end of a page when this document was last saved by an application which paginates its content.

[*Guidance*: This element shall be used by applications to specify the locations of page breaks within a document when it is saved as WordprocessingML, in order to allow other applications (e.g. assistive software) to utilize this information when reading the document. *end guidance*]

[*Example*: Consider a run which consists of the text `This is the end of the page`, where the word `end` was the last word on a page. If the application saving this file had paginated this content, that information may be saved with the file as follows:

```
<w:r>
  <w:t>This is the end</w:t>
  <w:lastRenderedPageBreak/>
  <w:t xml:space="preserve"> of the page</w:t>
</w:r>
```

The lastRenderedPageBreak element indicates that there was a page break resulting from pagination of this content, which occurred between the word `end` and the word `of`. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.14 lid (Language ID for Phonetic Guide)

This element specifies the language which shall be for this phonetic guide.

[*Example*: Consider a run of phonetic guide text which is using Japanese as it language. This constraint is specified using the following WordprocessingML:

```
<w:rubyPr>
  …
  <w:lid w:val="ja-JP"/>
```

```
    …
</w:rubyPr>
```

The lid property is `ja-JP` for the phonetic guide, so the phonetic guide is specified to be Japanese. *end example*]

Parent Elements
rubyPr (§2.3.3.27)

Attributes	Description
val (Language Code)	Specifies an ISO 639-1 letter code or 4 digit hexadecimal code for a specific language. This code is interpreted in the context of the parent XML element. [*Example*: Consider an object which shall specify the English(Canada) language. That object would use the ISO 639-1 letter code of `en-CA` to specify this language. *end example*] The possible values for this attribute are defined by the ST_Lang simple type (§2.18.51).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Lang">
   <attribute name="val" type="ST_Lang" use="required"/>
</complexType>
```

2.3.3.15 monthLong (Date Block - Long Month Format)

This element specifies the presence of a date block at the current location in the run content. A *date block* is a non-editable region of text which shall display the current date filtered through the specified date picture (see following paragraphs) . [*Note*: The date block is a legacy construct used for compatibility with older word processors, and should not be produced unless it was consumed while reading a document – it is recommended that the DATE field is used in its place. *end note*]

A date block shall be displayed using the primary editing language of the host application, regardless of the languages specified in the parent run's lang property (§2.3.2.18).

The long month format date block shall use a date picture of `MMMM`, retrieving the long month format for the primary editing language.

[*Example*: Consider a WordprocessingML run with the following run content:

```
<w:r>
  <w:t xml:space="preserve">This is a long date: </w:t>
  <w:monthLong />
</w:r>
```

This run specifies that a long month format date block shall be placed after the text string literal `This is a long date:` in the document. Assuming that the host application's primary editing language is French (Canada) and today's date is 04/12/2006 (a Wednesday), this run would be displayed as follows:

```
This is a long date: avril
```

end example]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.16 monthShort (Date Block - Short Month Format)

This element specifies the presence of a date block at the current location in the run content. A *date block* is a non-editable region of text which shall display the current date filtered through the specified date picture (see following paragraphs). [*Note*: The date block is a legacy construct used for compatibility with older word processors, and should not be produced unless it was consumed while reading a document – it is recommended that the DATE field is used in its place. *end note*]

A date block shall be displayed using the primary editing language of the host application, regardless of the languages specified in the parent run's lang property (§2.3.2.18).

The short month format date block shall use a date picture of `MM`, retrieving the short month format for the primary editing language.

[*Example*: Consider a WordprocessingML run with the following run content:

```
<w:r>
  <w:t xml:space="preserve">This is a short date: </w:t>
  <w:monthShort />
</w:r>
```

This run specifies that a short month format date block shall be placed after the text string literal `This is a short date:` in the document. Assuming that the host application's primary editing language is English (Canada) and today's date is 04/12/2006 (a Wednesday), this run would be displayed as follows:

```
This is a short date: 04
```

end example]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.17 movie (Embedded Video)

This element specifies a location within a document where the specified parent image shall be treated as a static placeholder for an embedded movie. The specified movie file's contents should be displayed when requested at this location in the document. The location of the embedded movie to be displayed when supported shall be specified by the relationship whose Id attribute matches the id attribute on this element.

If the relationship type of the relationship specified by this element is not http://schemas.openxmlformats.org/officeDocument/2006/movie, or is not present, then the document shall be considered non-conformant. If an application cannot process external content of the content type specified by the targeted part, then it may be ignored.

[*Example*: Consider a WordprocessingML document which contains a VML shape holding the static image for a movie:

```
<v:shape id="_x0000_s1026" … >
  <w:movie r:id="rIdMovie" />
  <v:imagedata r:id="rId5" r:pict="rId6" o:title="" o:movie="7168" />
</v:shape>
```

The movie element specifies that the part targeted by the relationship with an ID of `rIdMovie` shall be imported at the beginning of the document. Examining the contents of the corresponding relationship part item, we can see the targets for that relationship:

```
<Relationships … >
  …
  <Relationship Id="rIdMovie" TargetMode="Internal"
Type="http://schemas.openxmlformats.org/officeDocument/2006/relationships/movie"
Target="movie.mov" />
  …
</Relationships>
```

The corresponding relationship part item shows that the movie file is located next to the main document and is named `movie.mov`. *end example*]

Parent Elements
pict (§2.3.3.21); pict (§2.9.23)

Attributes	Description
id (Relationship to Part)	Specifies the relationship ID to a specified part.

Attributes	Description
Namespace: .../officeDocument/2006/relationships	The specified relationship shall match the type required by the parent element: • http://schemas.openxmlformats.org/officeDocument/2006/relationships/footer for the footerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/header for the headerReference element • http://schemas.openxmlformats.org/officeDocument/2006/relationships/font for the embedBold, embedBoldItalic, embedItalic, or embedRegular elements • http://schemas.openxmlformats.org/officeDocument/2006/relationships/printerSettings for the printerSettings element [*Example*: Consider an XML element which has the following id attribute: `<… r:id="rId10" />` The markup specifies the associated relationship part with relationship ID `rId1` contains the corresponding relationship information for the parent XML element. *end example*] The possible values for this attribute are defined by the ST_RelationshipId simple type (§7.8.2.1).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Rel">
   <attribute ref="r:id" use="required"/>
</complexType>
```

2.3.3.18 noBreakHyphen (Non Breaking Hyphen Character)

This element specifies that a non breaking hyphen character shall be placed at the current location in the run content. A *non breaking hyphen* is the equivalent of Unicode character 002D (the hyphen-minus), however it shall not be used as a valid line breaking character for the current line of text when displaying this WordprocessingML content.

The behavior of a non breaking hyphen in run content shall be to display using the same glyph as the hyphen-minus character, however without being a valid line breaking position (unlike the hyphen-minus character).

[*Example*: Consider the following sentence in a WordprocessingML document:

`This makes a very very very wordy and deliberately overcomplicated sentence.`

Normally, just as shown above, this sentence not would be displayed on a single line as it is long enough to require line breaking (given the width of the current page). However, if a hyphen minus were inserted after the letter s in `sentence`, as follows:

```
<w:r>
  <w:t>This makes a very very very wordy and deliberately overcomplicated s-
entence.</w:t>
</w:r>
```

This would allow a break at that position, and break the word after that character:

```
This makes a very very very wordy and deliberately overcomplicated s-entence.
```

If this was not desired, the non breaking hyphen character could be specified as follows:

```
<w:r>
  <w:t>This makes a very very very wordy and deliberately overcomplicated
s</w:t>
  <w:nonBreakHyphen/>
  <w:t>entence.</w:t>
</w:r>
```

This would display a hyphen character, but would not allow the text to break at that location:

```
This makes a very very very wordy and deliberately overcomplicated s-entence.
```

end example]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.19 object (Inline Embedded Object)

This element specifies that an embedded object is located at this position in the run's contents. The layout properties of this embedded object are specified using the VML syntax (§6.1).

[*Example*: Consider a run which consists of an embedded object which is in line with the text in that paragraph (i.e. on the line and affects the line height). That run would be specified using the following WordprocessingML:

```
<w:r>
  <w:object>
    …
  </w:object>
</w:r>
```

The object element indicates that an embedded object and its VML positioning data are located at the current position in the run (e.g. an embedded object). *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Child Elements	Subclause
Any element from the urn:schemas-microsoft-com:vml namespace	§6.1
Any element from the urn:schemas-microsoft-com:office:office namespace	§6.2
control (Inline Embedded Control)	§2.3.3.3

Attributes	Description

dxaOrig (Original Image Width)	Specifies the original (natural) width of the image representation of the current control within the document. Some vector image formats do not store a native size within their format, and this attribute shall only be used in those cases to store this information, so that the image may be appropriately restored as needed.
	
	If this element is excluded, then the natural size of the image as stored in its format shall be used.
	
	[*Example*: Consider the following WordprocessingML for an embedded object:
	
	`<w:object w:dxaOrig="3360" w:dyaOrig="2520">`
	`  …`
	`  <v:shape … style="width:168pt;height:4in">`
	`  …`
	`  </v:shape>`
	`  <o:OLEObject … />`
	`</w:object>`
	
	The dxaOrig attribute has a value of 3360, which specifies that the image used for the embedded object doesn't store its native width, but that width should be 3360 twentieths of a point. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

dyaOrig (Original Image Height)	Specifies the original (natural) height of the image representation of the current control within the document. Some vector image formats do not store a native size within their format, and this attribute shall only be used in those cases to store this information, so that the image may be appropriately restored as needed. If this element is excluded, then the natural size of the image as stored in its format shall be used. [*Example*: Consider the following WordprocessingML for an embedded object:

Attributes	Description
	<w:object w:dxaOrig="3360" w:dyaOrig="2520"> … <v:shape … style="width:168pt;height:4in"> … </v:shape> <o:OLEObject … /> </w:object> The dyaOrig attribute has a value of 2520, which specifies that the image used for the embedded object doesn't store its native height, but that height should be 2520 twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Object">
   <complexContent>
      <extension base="CT_PictureBase">
         <sequence>
            <element name="control" type="CT_Control" minOccurs="0"/>
         </sequence>
         <attribute name="dxaOrig" type="ST_TwipsMeasure" use="optional"/>
         <attribute name="dyaOrig" type="ST_TwipsMeasure" use="optional"/>
      </extension>
   </complexContent>
</complexType>
```

2.3.3.20 pgNum (Page Number Block)

This element specifies the presence of a page number block at the current location in the run content. A *page number block* is a non-editable region of text which shall display the current page using ascending decimal numbers. [*Note*: The page number block is a legacy construct used for compatibility with older word processors, and should not be produced unless it was consumed while reading a document – it is recommended that the PAGENUM field is used in its place. *end note*]

A page number block shall be displayed using ascending decimal numbers, regardless of the languages specified in the parent run's lang property (§2.3.2.18).

[*Example*: Consider a WordprocessingML run with the following run content:

```
<w:r>
  <w:t xml:space="preserve">This is the current page: </w:t>
  <w:pgNum />
</w:r>
```

This run specifies that a page number block shall be placed after the text string literal `This is the curent page:` in the document. Assuming that this content is on the first page, this run would be displayed as follows:

```
This is the current page: 1
```

end example]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.21 pict (VML Object)

This element specifies that an object is located at this position in the run's contents. The layout properties of this object are specified using the VML syntax (§6.1).

[*Example*: Consider a run which consists of an object specified using VML. That run would be specified using the following WordprocessingML:

```
<w:r>
  <w:pict>
    …
  </w:pict>
</w:r>
```

The pict element indicates that an object specified in VML is located at the current position in the run (e.g. a floating embedded control). *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Child Elements	Subclause
Any element from the urn:schemas-microsoft-com:vml namespace	§6.1
Any element from the urn:schemas-microsoft-com:office:office namespace	§6.2
control (Floating Embedded Control)	§2.3.3.2
movie (Embedded Video)	§2.3.3.17

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Picture">
   <complexContent>
      <extension base="CT_PictureBase">
         <sequence maxOccurs="1">
            <element name="movie" type="CT_Rel" minOccurs="0"/>
            <element name="control" type="CT_Control" minOccurs="0"/>
         </sequence>
      </extension>
   </complexContent>
</complexType>
```

2.3.3.22 ptab (Absolute Position Tab Character)

This element specifies that an absolute position tab character shall be placed at the current location in the run content. An *absolute position tab* is a character which is used to advance the position on the current line of text when displaying this WordprocessingML content, using the following logic:

Regardless of any number of custom tab stops defined using the tabs element (§2.3.1.38) , the absolute position tab character shall advance to the position specified by its alignment and relativeTo attributes. The resulting end position of the tab character shall not be affected by the addition of any custom tab stops or changes to the value of the defaultTabStop element (§2.15.1.24).

If the alignment location specified by the positional tab cannot be found on the current line, because the starting location is past that point, then the tab character shall advance to that location on the next available line in the document.

[*Example*: Consider a paragraph which contains two custom tab stops at 1.5" and 3.5", respectively. These two tab stops would be contained within a tabs element defining the set of tab stops of the paragraph as follows:

```
<w:pPr>
  <w:tabs>
    <w:tab w:val="left" w:pos="2160" />
    <w:tab w:val="left" w:pos="5040" />
  </w:tabs>
</w:pPr>
```

If a positional tab character was added to a run in this paragraph starting at 1” inside the margin and was defined as follows:

```
<w:ptab w:alignment="center" w:relativeTo="margin" />
```

This positional tab would then ignore the next custom tab stop and the indents on the current paragraph defined using the ind element (§2.3.1.12) and would advance to the center of the line with respect to the text margins, moving to a new line if needed. *end example*]

Parent Elements

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Attributes	Description
alignment (Positional Tab Stop Alignment)	Specifies the location of the positional tab stop on the line, as well as the alignment which shall be applied to text subsequent to the current positional tab stop. [*Example*: Consider a positional tab stop in a WordprocessingML document who shall move to the left edge of the text margins and whose subsequent text should be left aligned. This positional tab stop would be defined as follows: `<w:ptab w:alignment="left" w:relativeTo=”margin” … />` The alignment attribute specifies that this absolute position tab stop shall align on the left edge of the line relative to the margin. *end example*] The possible values for this attribute are defined by the ST_PTabAlignment simple type (§2.18.78).
leader (Tab Leader Character)	Specifies the character which shall be used to fill in the space created by a positional tab. This character shall be repeated as required to completely fill the tab spacing generated by the positional tab character. [*Example*: Consider a positional tab stop which should be preceded by a sequence of underscore characters, as follows: _____Text at the positional tab stop This tab stop would have a leader attribute value of `underscore`, indicating that the tab stop shall be preceded by underscore characters as needed to fill the tab spacing. *end example*] The possible values for this attribute are defined by the ST_PTabLeader simple type (§2.18.79).
relativeTo (Positional Tab Base)	Specifies the extents which shall be used to calculate the absolute positioning of this positional tab character. [*Example*: Consider a positional tab stop in a WordprocessingML document that should have a resulting position that is centered on the text margins, ignoring both any custom tab stops and any text indents on the paragraph. This positional tab stop would be defined as follows: `<w:ptab w:relativeTo="margin" … />` The relativeTo attribute specifies that this absolute position tab stop shall be relative to the margin. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_PTabRelativeTo simple type (§2.18.80).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_PTab">
   <attribute name="alignment" type="ST_PTabAlignment" use="required"/>
   <attribute name="relativeTo" type="ST_PTabRelativeTo" use="required"/>
   <attribute name="leader" type="ST_PTabLeader" use="required"/>
</complexType>
```

2.3.3.23 rt (Phonetic Guide Text)

This element specifies the presence of the guide text within a phonetic guide at the current location in the document.

The contents of the guide text run are specified in the child r element (§2.3.2.23).

[*Example*: Consider the following two runs, each containing a phonetic guide:

tōkyō
東京

The guide text run would be specified using the following WordprocessingML:

```
<w:rt>
  …
  <w:r>
    <w:t>tō</w:t>
  </w:r>
</w:rt>
```

The guide text is contained in a run within the rt element. *end example*]

permStart (Range Permission Start)	§2.13.7.2
proofErr (Proofing Error Anchor)	§2.13.8.1
r (Text Run)	§2.3.2.23

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RubyContent">
    <group ref="EG_RubyContent" minOccurs="0" maxOccurs="unbounded"/>
</complexType>
```

2.3.3.24 ruby (Phonetic Guide)

This element specifies the presence of a phonetic guide at the current location in the document. A *phonetic guide* (often called ruby text) is a run of content with base text which appears at the normal baseline location for text in this run, with phonetic guide text displayed above it in the document. The resulting construct is called a phonetic guide as it is typically used to map words in one language to another phonetically.

The base text is stored in the rubyBase element (§2.3.3.26) and the guide text is stored in the rt element (§2.3.3.23).

[*Example*: Consider the following two runs, each containing a phonetic guide:

tōkyō
東京

The first run would be specified using the following WordprocessingML:

```
<w:r>
  <w:ruby>
    <w:rubyPr>
       …
    </w:rubyPr>
    <w:rt>
      …
      <w:r>
        <w:t>tō</w:t>
      </w:r>
    </w:rt>
    <w:rubyBase>
      …
      <w:r>
        <w:t>東/w:t>
      </w:r>
    </w:rubyBase>
  </w:ruby>
</w:r>
```

The base text is contained in a run within the rubyBase element, and the guide text is contained in a run within the rt element. end example]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Child Elements	Subclause
rt (Phonetic Guide Text)	§2.3.3.23
rubyBase (Phonetic Guide Base Text)	§2.3.3.26
rubyPr (Phonetic Guide Properties)	§2.3.3.27

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Ruby">
   <sequence>
      <element name="rubyPr" type="CT_RubyPr"/>
      <element name="rt" type="CT_RubyContent"/>
      <element name="rubyBase" type="CT_RubyContent"/>
   </sequence>
</complexType>
```

2.3.3.25 rubyAlign (Phonetic Guide Text Alignment)

This element specifies the alignment setting which shall be used to determine the placement of phonetic guide text with respect to the base text when this phonetic guide is displayed.

[*Example*: Consider a run of phonetic guide text which shall have the ruby text positioned to the far left of the base text. This constraint is specified using the following WordprocessingML:

```
<w:rubyPr>
  …
  <w:rubyAlign w:val="left"/>
  …
</w:rubyPr>
```

The rubyAlign property is `left` for the phonetic guide, so the ruby text will be displayed on the left side of the base text. *end example*]

Parent Elements
rubyPr (§2.3.3.27)

Attributes	Description

val (Phonetic Guide Text Alignment Value)	Specifies the type of alignment to be applied to the phonetic guide text.
	
	[*Example*: Consider a run of phonetic guide text which shall have the ruby text positioned to the far right of the base text. This constraint is specified using the following WordprocessingML:
	
	`<w:rubyPr>`
	`  …`
	`  <w:rubyAlign w:val="left"/>`
	`  …`
	`</w:rubyPr>`
	
	The value of the val attribute is `right` for the phonetic guide, so the ruby text will be displayed on the right side of the base text. *end example*]
	
	The possible values for this attribute are defined by the ST_RubyAlign simple type (§2.18.82).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RubyAlign">
   <attribute name="val" type="ST_RubyAlign" use="required"/>
</complexType>
```

2.3.3.26 rubyBase (Phonetic Guide Base Text)

This element specifies the presence of the base text within a phonetic guide at the current location in the document.

The contents of the base text run are specified in the child r element (§2.3.2.23).

[*Example*: Consider the following two runs, each containing a phonetic guide:

tōkyō
東京

The base text run would be specified using the following WordprocessingML:

```
<w:rubyBase>
  …
  <w:r>
    <w:t>東</w:t>
  </w:r>
</w:rubyBase>
```

The base text is contained in a run within the rubyBase element. *end example*]

Parent Elements
ruby (§2.3.3.24)

permStart (Range Permission Start)	§2.13.7.2
proofErr (Proofing Error Anchor)	§2.13.8.1
r (Text Run)	§2.3.2.23

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RubyContent">
   <group ref="EG_RubyContent" minOccurs="0" maxOccurs="unbounded"/>
</complexType>
```

2.3.3.27 rubyPr (Phonetic Guide Properties)

This element specifies a set of properties which determine the behavior and appearance of a phonetic guide within the document.

[*Example*: Consider the following two runs, each containing a phonetic guide:

tōkyō
東京

The properties for both of these phonetic guides are as follows:

```
<w:r>
  <w:ruby>
    <w:rubyPr>
      <w:rubyAlign w:val="distributeSpace" />
      <w:hps w:val="16" />
      <w:hpsRaise w:val="20" />
      <w:hpsBaseText w:val="22" />
      <w:lid w:val="ja-JP" />
    </w:rubyPr>
    …
  </w:ruby>
</w:r>
```

The phonetic guide properties specify that the guide text shall be:

- Distributed across the top (using the rubyAlign element)
- 8 point font face (using the hps element)
- 10 points above the base text (using the hpaRaise element)
- Japanese (using the lid element)

As well, the phonetic guide properties specify that the base text shall be:

- 11 point font face (using the hpsBaseText element)

end example]

Parent Elements
ruby (§2.3.3.24)

Child Elements	Subclause
dirty (Invalidated Field Cache)	§2.3.3.8
hps (Phonetic Guide Text Font Size)	§2.3.3.10
hpsBaseText (Phonetic Guide Base Text Font Size)	§2.3.3.11
hpsRaise (Distance Between Phonetic Guide Text and Phonetic Guide Base Text)	§2.3.3.12
lid (Language ID for Phonetic Guide)	§2.3.3.14
rubyAlign (Phonetic Guide Text Alignment)	§2.3.3.25

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_RubyPr">
   <sequence>
      <element name="rubyAlign" type="CT_RubyAlign"/>
      <element name="hps" type="CT_HpsMeasure"/>
      <element name="hpsRaise" type="CT_HpsMeasure"/>
      <element name="hpsBaseText" type="CT_HpsMeasure"/>
      <element name="lid" type="CT_Lang"/>
      <element name="dirty" type="CT_OnOff" minOccurs="0"/>
   </sequence>
</complexType>
```

2.3.3.28 softHyphen (Optional Hyphen Character)

This element specifies that an optional hyphen character shall be placed at the current location in the run content. An *optional hyphen* is a character which may be used as a valid line breaking character for the current line of text when displaying this WordprocessingML content, using the following logic:

- When this character is not the character which is used to break the line, then it shall not change the normal display of text (it shall have zero width)

- When this character is the character used to break the line, it shall display using the hyphen-minus character within the display of text

[*Note*: This character is typically used to mark locations where a word may optionally be hyphenated without causing the hyphen character to be displayed unnecessarily. *end note*]

[*Example*: Consider the following sentence in a WordprocessingML document:

```
This sentence needs to be long enough to cause some kind of line breaking.
```

Normally, just as shown above, this sentence not would be displayed on a single line as it is long enough to require line breaking (given the width of the current page). However, if an optional hyphen were inserted after the letter r in `breaking`, as follows:

```
<w:r>
  <w:t>This sentence needs to be long enough to cause some kind of line br</w:t>
  <w:softHyphen/>
  <w:t>eaking.</w:t>
</w:r>
```

This would allow a break at that position, and when that location is the point of the line break, would insert a hyphen-minus in the word after that character:

```
This sentence needs to be long enough to cause some kind of line breaking.
```

If this was not the point of the line break, then no character would be displayed at that location:

```
This sentence should not be long enough to cause line breaking.
```

The sentence now does not break at that location, so no hyphen appears in the word `breaking`. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.29 sym (Symbol Character)

This element specifies the presence of a symbol character at the current location in the run's content. A *symbol character* is a special character within a run's content which does not use any of the run fonts specified in the rFonts element (§2.3.2.24) (or by the style hierarchy).

Instead, this character shall be determined by pulling the character with the hexadecimal value specified in the char attribute from the font specified in the font attribute.

[*Example*: Consider a run containing the following run content:

```
This is a symbol character:💻
```

The last character in that run is a symbol character from the Wingdings font, and the run is specified as follows:

```
<w:r>
  <w:rPr>
    <w:rFonts w:ascii="Courier New" w:hAnsi="Courier New" />
  </w:rPr>
  <w:t>This is a symbol character:</w:t>
  <w:sym w:font="Wingdings" w:code="F03A" />
</w:r>
```

The resulting symbol is the specified using the sym element, and consists of character code `003A` formatted as `Wingdings`, even though the run properties specify the `Courier New` font. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Attributes	Description

char (Symbol Character Code)	Specifies the hexadecimal code for the Unicode character value of the symbol.
	
	When this value is stored in the char attribute, it may be stored in either of the following two formats:
	1. Directly in its Unicode character value from the font glyph
	2. In a Unicode character value created by adding F000 to the actual character value, shifting the character value of this character into the Unicode private use area.
	
	[*Note*: The use of the latter syntax allows for interoperability with legacy word processing formats, as they used this technique to store the fact that a particular character or set of characters came from a font which was not Unicode compliant, and therefore any font matching performed on this range (if the specified font was not present) would be undesirable, as the resulting glyphs and their appearance could not be predicted. *end note*]
	
	[*Example*: Consider a run with a single symbol character defined as follows:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:rFonts w:ascii="Arial Black" w:hAnsi="Arial Black" />`
	`  </w:rPr>`
	`  <w:sym w:font="Wingdings" w:char="F045" />`
	`</w:r>`
	
	The symbol character shall use the font defined in its font attribute and hence use the

Attributes	Description
	Wingdings font. The character value for the character to be used from this font is obtained by removing the F000 value from the value in the char attribute, and therefore is the character at hexadecimal position 0045 in that font. *end example*] The possible values for this attribute are defined by the ST_ShortHexNumber simple type (§2.18.86).

font (Symbol Character Font)	Specifies a font which shall be used to format this symbol character.
	
	[*Example*: Consider a run with a single symbol character defined as follows:
	
	`<w:r>`
	`  <w:rPr>`
	`  <w:rFonts w:ascii="Arial Black" w:hAnsi="Arial Black" />`
	`  </w:rPr>`
	`  <w:sym w:font="Wingdings" w:char="F045" />`
	`</w:r>`
	
	Although the run specifies that its contents shall use the Arial Black font, the symbol character shall use the font defined in its font attribute and hence use the Wingdings font. *end example*]
	
	The possible values for this attribute are defined by the ST_String simple type (§2.18.89).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Sym">
   <attribute name="font" type="ST_String"/>
   <attribute name="char" type="ST_ShortHexNumber"/>
</complexType>
```

2.3.3.30 t (Text)

This element specifies that this run contains literal text which shall be displayed in the document. The t element shall be used for all text runs which is not:

- Part of a region of text that is contained in a deleted region using the del element (§2.13.5.12)
- Part of a region of text that is contained within a field code

[*Example*: Consider a paragraph of WordprocessingML content which reads This is text. This paragraph would therefore be represented as follows:

```
<w:p>
  <w:r>
    <w:t>This is text</w:t>
  </w:r>
</w:p>
```

The text is contained in a t node. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

Attributes	Description

space (Content Contains Significant Whitespace)
 	
Namespace: http://www.w3.org/XML/1998/namespace
	Specifies how white space should be handled for the contents of this element using the W3C space preservation rules.
	
	[*Example*: Consider the following run contained within a WordprocessingML document:
	
	`<w:r>`
	`  <w:t>significant whitespace  </w:t>`
	`</w:r>`
	
	Although there are three spaces on each side of the text content in the run, that whitespace has not been specifically marked as significant, therefore it is removed when this run is added to the document. *end example*]
	
	The possible values for this attribute are defined by the type in the namespace.

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Text">
   <simpleContent>
      <extension base="ST_String">
         <attribute ref="xml:space" use="optional"/>
      </extension>
   </simpleContent>
</complexType>
```

2.3.3.31 tab (Tab Character)

This element specifies that a tab character shall be placed at the current location in the run content. An *tab* is a character which is used to advance the position on the current line of text when displaying this WordprocessingML content, using the following logic:

- When there are one or more custom tab stops defined using the tabs element (§2.3.1.38) , then the tab character shall advance to the next custom tab stop location which is further along than the starting location of the tab
- When there are no custom tab stops which are further than the current position in the line, the tab character shall advance to the nearest multiple of the defaultTabStop element (§2.15.1.24) width value.

[*Example*: Consider a paragraph which contains two custom tab stops at 1.5" and 3.5", respectively. These two tab stops would be contained within a tabs element defining the set of tab stops of the paragraph as follows:

```
<w:pPr>
```

```
    <w:tabs>
      <w:tab w:val="left" w:pos="2160" />
      <w:tab w:val="left" w:pos="5040" />
    </w:tabs>
  </w:pPr>
```

If a tab character was added to a run in this paragraph and appeared 1.4” along the line after all preceding content was laid out, then this tab would move the position to 1.5”. If the tab character appeared 1.6” along the line after all preceding content was laid out, then this tab would move the position to 3.5”. In both cases, the tab advanced to the next custom tab stop. *end example*]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.32 yearLong (Date Block - Long Year Format)

This element specifies the presence of a date block at the current location in the run content. A *date block* is a non-editable region of text which shall display the current date filtered through the specified date picture (see following paragraphs). [*Note*: The date block is a legacy construct used for compatibility with older word processors, and should not be produced unless it was consumed while reading a document – it is recommended that the DATE field is used in its place. *end note*]

A date block shall be displayed using the primary editing language of the host application, regardless of the languages specified in the parent run’s lang property (§2.3.2.18).

The long year format date block shall use a date picture of YYYY, retrieving the long year format for the primary editing language.

[*Example*: Consider a WordprocessingML run with the following run content:

```
<w:r>
  <w:t xml:space="preserve">This is a long date: </w:t>
  <w:yearLong />
</w:r>
```

This run specifies that a long year format date block shall be placed after the text string literal `This is a long date:` in the document. Assuming that the host application’s primary editing language is English (Canada) and today’s date is 04/12/2006 (a Wednesday), this run would be displayed as follows:

```
This is a long date: 2006
```

end example]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.3.3.33 yearShort (Date Block - Short Year Format)

This element specifies the presence of a date block at the current location in the run content. A *date block* is a non-editable region of text which shall display the current date filtered through the specified date picture (see following paragraphs). [*Note*: The date block is a legacy construct used for compatibility with older word processors, and should not be produced unless it was consumed while reading a document – it is recommended that the DATE field is used in its place. *end note*]

A date block shall be displayed using the primary editing language of the host application, regardless of the languages specified in the parent run's lang property (§2.3.2.18).

The short year format date block shall use a date picture of YY, retrieving the short year format for the primary editing language.

[*Example*: Consider a WordprocessingML run with the following run content:

```
<w:r>
  <w:t xml:space="preserve">This is a short date: </w:t>
  <w:yearShort />
</w:r>
```

This run specifies that a short year format date block shall be placed after the text string literal `This is a short date:` in the document. Assuming that the host application's primary editing language is French (Canada) and today's date is 04/12/2006 (a Wednesday), this run would be displayed as follows:

```
This is a short date: 06
```

end example]

Parent Elements
r (§7.1.2.87); r (§2.3.2.23)

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Empty"/>
```

2.4 Tables

Another type of block-level content in WordprocessingML, a *table* is a set of paragraphs (and other block-level content) arranged in *rows* and *columns*. Tables in WordprocessingML are defined via the tbl element, which is

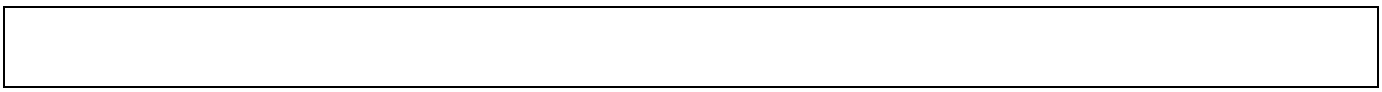
analogous to the HTML <table> tag. The table element specifies the location of a table present in the document.

A tbl element (§2.4.36) has two elements that define its properties:

- tblPr (§2.4.55), which defines the set of table-wide properties (such as style and width)
- tblGrid (§2.4.44), which defines the grid layout of the table.

A tbl element can also contain an arbitrary non-zero number of rows, where each row is specified with a tr element (§2.4.75). Each tr element can contain an arbitrary non-zero number of cells, where each cell is specified with a tc element (§2.4.62).

[*Example*: Consider an empty one-cell table (i.e.; a table with one row, one column) and 1 point borders on all sides as follows:



This table is represented by the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblW w:w="5000" w:type="pct"/>
    <w:tblBorders>
      <w:top w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:left w:val="single" w:sz="4 w:space="0" w:color="auto"/>
      <w:bottom w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:right w:val="single" w:sz="4" w:space="0" w:color="auto"/>
    </w:tblBorders>
  </w:tblPr>
  <w:tblGrid>
    <w:gridCol w:w="10296"/>
  </w:tblGrid>
  <w:tr>
    <w:tc>
      <w:tcPr>
        <w:tcW w:w="0" w:type="auto"/>
      </w:tcPr>
      <w:p/>
    </w:tc>
  </w:tr>
</w:tbl>
```

This table specifies table-wide properties of 100% of page width using the tblW element and the set of table borders using the tblBorders element, the table grid which defines a set of shared vertical edges within the table using the tblGrid element, and a single row using the tr element. *end example*]

2.4.1 bidiVisual (Visually Right to Left Table)

This element specifies that the cells with this table shall be visually represented in a right to left direction. This element also affects the application of all table-level properties.

When this property is specified, then the ordering of all cells (and table-level properties) in this table shall be applied to the table assuming that the table is a normal left to right table, but the table cells shall be displayed in a right to left direction. [*Example*: A left border on the first table cell shall be displayed on the right side of that cell (which would be the rightmost cell) in a visually right to left table. *end example*]

If this element is omitted, then the table shall not be presented right to left.

[*Example*: Consider the following table which has the logical right to left property set:

	Three	Two	One

This property would be specified in the WordprocessingML as follows:

```
<w:tblPr>
  <w:bidiVisual/>
</w:tblPr>
```

Since the bidiVisual element specifies this is a visually right to left table, the actual table data would be stored in its logical order as follows:

```
<w:tr>
  <w:tc>
    <w:p>
      <w:r>
        <w:t>One</w:t>
      </w:r>
    </w:p>
  </w:tc>
```

```
    <w:tc>
      <w:p>
        <w:r>
          <w:t>Two</w:t>
        </w:r>
      </w:p>
    </w:tc>
    <w:tc>
      <w:p>
        <w:r>
          <w:t>Three</w:t>
        </w:r>
      </w:p>
    </w:tc>
    <w:tc>
      <w:p/>
    </w:tc>
  </w:tr>
```

The first logical cell with text `One` is stored first in the file format, and displayed on the rightmost in this table visually. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of `on`, `1`, or `true` specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of `off`, `0`, or `false` specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned `off`. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.4.2 bottom (Table Cell Bottom Margin Exception)

This element specifies the amount of space which shall be left between the bottom extent of the cell contents and the border of a specific table cell within a table. This setting shall override the table cell bottom margin definition specified by the bottom element contained within the table properties (§2.4.5).

This value is specified in the units applied via its type attribute. Any width value of type pct or auto for this element shall be ignored.

If omitted, then this table cell shall use the bottom cell margins defined in the bottom element contained within the table properties (§2.4.5).

[*Example*: Consider a table with two cells in which the first table cell's bottom margin is specified via an exception to be ten times larger (0.2 inches vs. 0.02 inches) than the other table cell margins:

This text fills the extents of the cell.
So does this

The first cell in the table would be specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    <w:tcMar>
      <w:bottom w:w="288" w:type="dxa" />
    </w:tcMar>
  </w:tcPr>
</w:tc>
```

The first cell in this table has an exception applied to the table cell bottom cell margin setting it to 288 twentieths of a point (0.2 inches). *end example*]

Parent Elements
tcMar (§2.4.65)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins.

Attributes	Description
	If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.3 bottom (Table Cell Bottom Border)

This element specifies the border which shall be displayed at the bottom of the current table cell. The appearance of this table cell border in the document shall be determined by the following settings:

- If the net tblCellSpacing element value (§2.4.41;§2.4.42;§2.4.43) applied to the cell is non-zero, then the cell border shall always be displayed

- Otherwise, the display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the bottom of this table cell shall not have a cell border, and its border may use the table's border settings as appropriate.

[*Example*: Consider a table in which the first cell in the first row specifies a bottom cell border

R1C1	R1C2
R2C1	R2C2

This bottom cell border is specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    …
    <w:tcBorders>
      <w:bottom w:val="thinThickThinSmallGap" w:sz="24" w:space="0"
w:color="FF0000"/>
    </w:tcBorders>
  </w:tcPr>
  <w:p/>
</w:tc>
```

The bottom element specifies a three point border of type `thinThinThickSmallGap`. *end example*]

Parent Elements
tcBorders (§2.4.63)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*]

Attributes	Description
	If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of

Attributes	Description

	text in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the

Attributes	Description

	document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB

Attributes	Description
	[*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `C0504D`. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L' = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$ and converting back to RGB, we get `943634`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $T_{xml} = 0.6 * 255$ $= 153$ $= 99(hex)$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows:

Attributes	Description
	$$L^{'} = L * Tint_{pct} + (1 - Tint_{pct})$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L^{'} = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.4 bottom (Table Bottom Border)

This element specifies the border which shall be displayed at the bottom of the current table. The appearance of this table border in the document shall be determined by the following settings:

- The display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the bottom of this table shall have the border specified by the associated table style. If no bottom border is specified in the style hierarchy, then this table shall not have a bottom border.

[*Example*: Consider a table in which the table properties specifies a bottom table border, as follows:

R1C1	R1C2
R2C1	R2C2

This bottom table border is specified using the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblBorders>
      <w:bottom w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="D0D0D0" w:themeColor="accent3" w:themeTint="99"/>
    </w:tblBorders>
  </w:tblPr>
  …
</w:tbl>
```

The bottom element specifies a three point bottom table border of type thinThinThickMediumGap. *end example*]

Parent Elements

Parent Elements
tblBorders (§2.4.37); tblBorders (§2.4.38)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect.

Attributes	Description
	[*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.

Attributes	Description

	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border.

Attributes	Description
	[*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 \\ = 102 \\ = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}^{'} = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L^{'} = 0.53 * 0.75 \\ = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from

Attributes	Description
	the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).

Attributes	Description
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.5 bottom (Table Cell Bottom Margin Default)

This element specifies the amount of space which shall be left between the bottom extent of the cell contents and the border of all table cells within the parent table (or table row). This setting may be overridden by the table cell bottom margin definition specified by the bottom element contained within the table cell's properties (§2.4.2).

This value is specified in the units applied via its type attribute. Any width value of type `pct` or `auto` for this element shall be ignored.

If this element is omitted, then it shall inherit the table cell margin from the associated table style. If a bottom margin is never specified in the style hierarchy, then this table shall have no bottom cell padding by default (excepting individual cell overrides).

[*Example*: Consider a two by two table in which the default table cell bottom margin is specified to be exactly 0.25 inches, as follows (marked with an arrow in the first table cell below):

R1C1 ↕	R2C1

R2C1	R2C2

This table property is specified using the following WordprocessingML markup:

```
<w:tbl>
  <w:tblPr>
    <w:tblCellMar>
      <w:bottom w:w="360" w:type="dxa"/>
    </w:tblCellMar>
  </w:tblPr>
  …
</w:tbl>
```

Every cell in the table has a default cell margin setting it to 360 twentieths of a point. *end example*]

Parent Elements
tblCellMar (§2.4.39); tblCellMar (§2.4.40)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows:

Attributes	Description
	<w:bottom w:w="302" w:type="dxa" /> The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

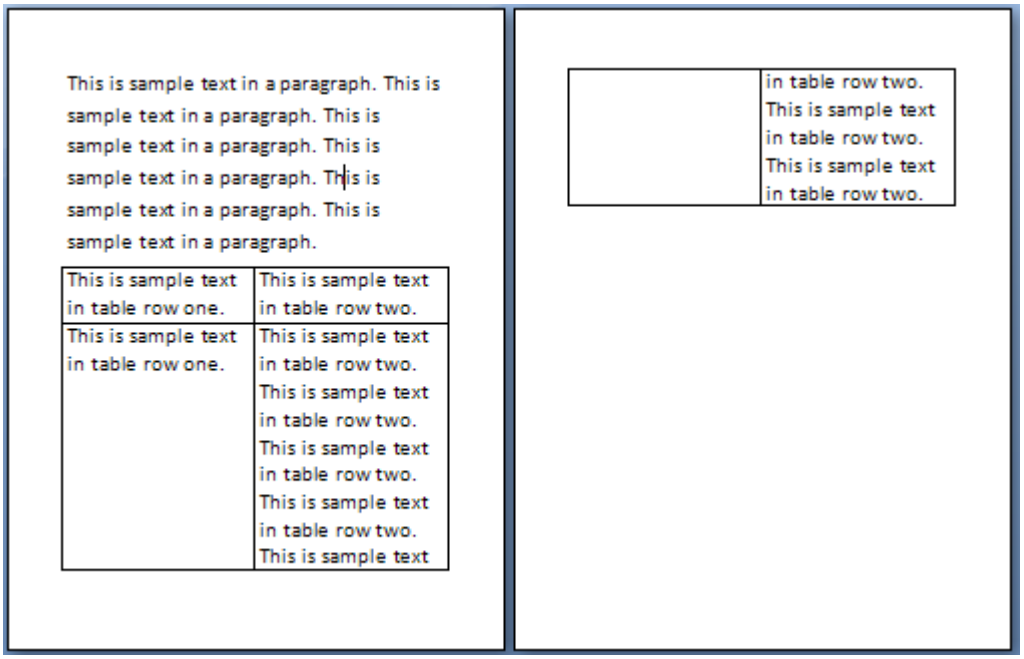
```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.6 cantSplit (Table Row Cannot Break Across Pages)

This element specifies whether the contents within the current cell shall be rendered on a single page. When displaying the contents of a table cell (such as the table cells in this specification), it is possible that a page break would fall within the contents of a table cell, causing the contents of that cell to be displayed across two different pages. If this property is set, then all contents of a table row shall be rendered on the same page by moving the start of the current row to the start of a new page if necessary. If the contents of this table row cannot fit on a single page, then this row shall start on a new page and flow onto multiple pages as necessary.

If this element is not present, the default behavior is dictated by the setting in the associated table style. If this property is not specified in the style hierarchy, then this table row shall be allowed to split across multiple pages.

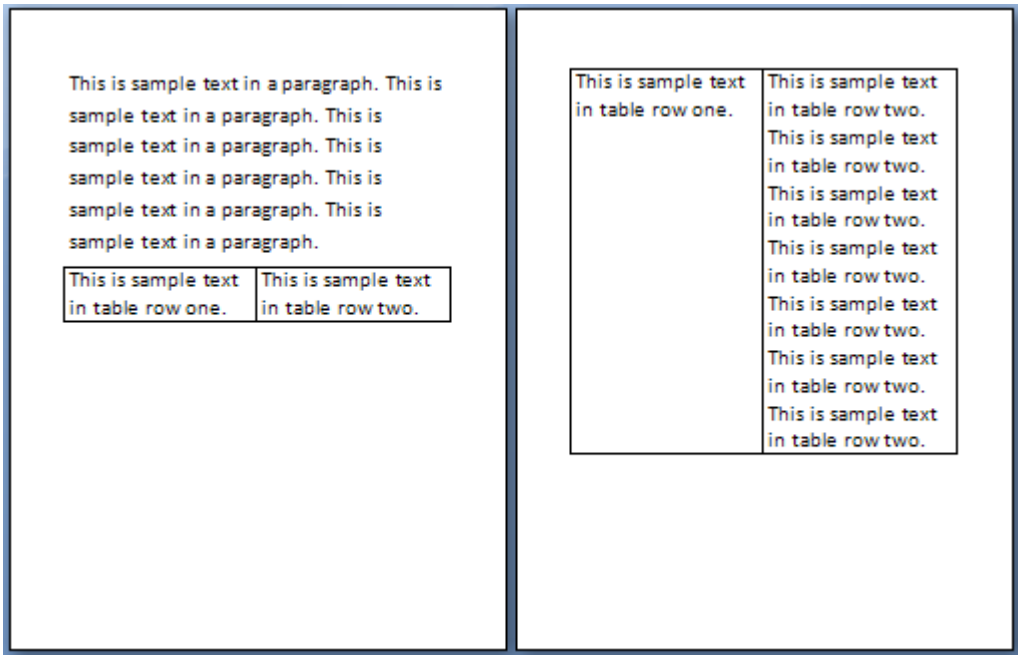
[*Example*: Consider the following content displayed on two different pages of a WordprocessingML document:



When this content is displayed, the contents of the 2nd table row in this document are displayed across two different pages. If the contents of this row are to be displayed on one page, then this requirement would be specified as follows:

```
<w:tr>
  <w:trPr>
    …
    <w:cantSplit />
  </w:trPr>
  …
</w:tr>
```

The presence of the cantSplit element specifies that the table row shall not be broken across multiple pages, therefore the second table row starts on a new page:



This setting therefore ensures that the content will always be displayed on a single page (if it fits on one page). *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.4.7 cnfStyle (Table Cell Conditional Formatting)

This element specifies the set of conditional table style formatting properties which have been applied to this table cell. [*Note*: This property is an optimization which is used by consumers to determine if a given property on a table cell is the result of the table style conditional formatting properties vs. direct formatting on the table cell itself. It specifies the components of the conditional formatting in the table style applied to this cell, so that the table's conditional formatting can be applied after the document is displayed without having the table style properties override the style hierarchy. *end note*]

If this element is omitted, then its value shall be assumed to be zero for all entries in the bit mask.

[*Example*: Consider a table cell in the top right corner of a table with a table style applied. This table cell would need to specify the following WordprocessingML to express that fact:

```
<w:tc>
  <w:tcPr>
    <w:cnfStyle w:val="101000000100" />
    …
  </w:tcPr>
  …
</w:tc>
```

This table cell specifies that it has the conditional properties from the table style for the first column, first row, and the top left corner of the parent table by setting the appropriate bits in the val attribute. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description
val (Conditional Formatting Bit Mask)	Specifies the set of conditional formatting properties that have been applied to this object. These properties are expressed using a string serialization of a binary bitmask for each of the following properties (reading from the first character position right): • First Row - Is this the first row of the table? • Last Row - Is this the last row of the table? • First Column - Does this belong to the first column of the table? • Last Column - Does this belong to the last column of the table? • Band 1 Vertical - Does this belong to a column which should receive band 1

Attributes	Description

	formatting? This property specifies whether the cell should receive the formatting specified for odd-numbered columns (e.g. 1,3,5,...)
	• Band 2 Vertical - Does this belong to a column which should receive band 2 formatting? This property specifies whether the cell should receive the formatting specified for even-numbered columns (e.g. 2,4,6...)
	• Band 1 Horizontal - Does this receive band 1 formatting? This property specifies whether the cell should receive the formatting specified for odd-numbered rows (e.g. 1,3,5,...)
	• Band 2 Horizontal - Does this receive band 2 formatting? This property specifies whether the cell should receive the formatting specified for even-numbered rows (e.g. 2,4,6...)
	• NE Cell - Is this part of the top-right corner of the table?
	• NW Cell - Is this part of the top-left corner of the table?
	• SE Cell - Is this part of the bottom-right corner of the table?
	• SW Cell - Is this part of the bottom-left corner of the table?
	
	For each of these properties, a value of 1 in the specified character position in the string means that the value is true, a value of 0 means false. All values must be specified.
	
	[*Example*: Consider a paragraph in the top right corner of a table with a table style applied. This paragraph would need to specify the following WordprocessingML:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:cnfStyle w:val="101000000100" />`
	`  ...`
	`  </w:pPr>`
	`  ...`
	`</w:p>`
	
	This paragraph specifies that it has the conditional properties from the table style for the first column, first row, and the NW corner of the parent table by setting the appropriate bits in the val attribute. *end example*]
	
	The possible values for this attribute are defined by the ST_Cnf simple type (§2.18.11).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Cnf">
    <attribute name="val" type="ST_Cnf" use="required"/>
</complexType>
```

2.4.8 cnfStyle (Table Row Conditional Formatting)

This element specifies the set of conditional table style formatting properties which have been applied to this table row. [*Note*: This property is an optimization which is used by consumers to determine if a given property on a table row is the result of the table style conditional formatting properties vs. direct formatting on the table

cell itself. It specifies the components of the conditional formatting in the table style applied to this cell, so that the table's conditional formatting can be applied after the document is displayed without having the table style properties override the style hierarchy. *end note*]

If this element is omitted, then its value shall be assumed to be zero for all entries in the bit mask.

[*Example*: Consider a table row in the top of a table with a table style applied. This table cell would need to specify the following WordprocessingML to express that fact:

```
<w:tr>
  <w:trPr>
    <w:cnfStyle w:val="100000000000" />
    …
  </w:trPr>
  …
</w:tr>
```

This table row specifies that it has the conditional properties from the table style for the first row of the parent table by setting the appropriate bits in the val attribute. *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
val (Conditional Formatting Bit Mask)	Specifies the set of conditional formatting properties that have been applied to this object. These properties are expressed using a string serialization of a binary bitmask for each of the following properties (reading from the first character position right): • First Row - Is this the first row of the table? • Last Row - Is this the last row of the table? • First Column - Does this belong to the first column of the table? • Last Column - Does this belong to the last column of the table? • Band 1 Vertical - Does this belong to a column which should receive band 1 formatting? This property specifies whether the cell should receive the formatting specified for odd-numbered columns (e.g. 1,3,5,...) • Band 2 Vertical - Does this belong to a column which should receive band 2 formatting? This property specifies whether the cell should receive the formatting specified for even-numbered columns (e.g. 2,4,6...) • Band 1 Horizontal - Does this receive band 1 formatting? This property specifies whether the cell should receive the formatting specified for odd-numbered rows (e.g. 1,3,5,...) • Band 2 Horizontal - Does this receive band 2 formatting? This property specifies

Attributes	Description

	whether the cell should receive the formatting specified for even-numbered rows (e.g. 2,4,6...)
	• NE Cell - Is this part of the top-right corner of the table?
	• NW Cell - Is this part of the top-left corner of the table?
	• SE Cell - Is this part of the bottom-right corner of the table?
	• SW Cell - Is this part of the bottom-left corner of the table?
	
	For each of these properties, a value of 1 in the specified character position in the string means that the value is true, a value of 0 means false. All values must be specified.
	
	[*Example*: Consider a paragraph in the top right corner of a table with a table style applied. This paragraph would need to specify the following WordprocessingML:
	
	`<w:p>`
	`  <w:pPr>`
	`  <w:cnfStyle w:val="101000000100" />`
	`  ...`
	`  </w:pPr>`
	`  ...`
	`</w:p>`
	
	This paragraph specifies that it has the conditional properties from the table style for the first column, first row, and the NW corner of the parent table by setting the appropriate bits in the val attribute. *end example*]
	
	The possible values for this attribute are defined by the ST_Cnf simple type (§2.18.11).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Cnf">
    <attribute name="val" type="ST_Cnf" use="required"/>
</complexType>
```

2.4.9 divId (Associated HTML div ID)

This element specifies the HTML div information which is associated with the current table row. This information, stored in the Web Settings part, is used to associate one or more table rows with a particular HTML `div` element. [*Note*: This property is used when saving an HTML document into the WordprocessingML format in order to prevent a loss of all HTML `div` information, so that the document can later be saved back into HTML format and have the stored information replaced, since the HTML `div` can store formatting properties on arbitrary regions. *end note*]

In order to determine the associated HTML `div` properties, the value of the val attribute on this element is used to look up an associated div element (§2.15.2.8) whose id attribute matches this value.

If this table row does not have a divId element present, then this table row shall not have any associated HTML div information. If this element is present, but the val attribute specifies an id value which does not have an associated div element, then this element is ignored.

[*Example*: Consider an HTML document defined as follows:

```
<html>
  <body>
    <div style="…">
      <table>
        <tr>
          <td>R1C1</td>
           …
        </tr>
      </table>
      <p>
        …
      </p>
    </div>
    …
  </body>
</html>
```

This HTML document specifies a div spanning the table and the first paragraph. If this document is saved into WordprocessingML, then both the rows of the table and the paragraph shall have a divId which points at the same div information in the web settings part:

```
<w:trPr>
  …
  <w:divId w:val="1102603671"/>
</w:trPr>
```

The val attribute then points at a div element which stores the associated div properties:

```
<w:divs>
  <w:div w:id="1102603671">
    …
  </w:div>
</w:divs>
```

This specifies that this table's rows are part of a single HTML div. *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.4.10 gridAfter (Grid Columns After Last Cell)

This element specifies the number of grid columns in the parent table's table grid (§2.4.44; §2.4.45) which shall be left after the last cell in the table row.

If this element conflicts with the remaining size of the document grid after all table cells in this row have been added to the grid, then it shall be ignored. If this element is not specified, then its value shall be assumed to be zero grid units.

[*Example*: Consider a table whose second row ends before the first row by one grid unit:

In this table, the second row leaves one grid unit after its cell contents, which is represented using the following WordprocessingML:

```
<w:tr>
  <w:trPr>
    <w:gridAfter w:val="1" />
    …
  </w:trPr>
  …
</w:tr>
```

The gridAfter element specifies that 1 grid unit remains after the row's contents. *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
    <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.4.11 gridBefore (Grid Columns Before First Cell)

This element specifies the number of grid columns in the parent table's table grid (§2.4.44; §2.4.45) which shall be skipped before the contents of this table row (its table cells) are added to the parent table. [*Note*: This property is used to specify tables whose leading edge (left for left-to-right tables, right for right-to-left tables) does not start at the first grid column (the same shared edge). *end note*]

If this element is omitted, then its value shall be assumed to be zero grid units. If this element's value is larger than the size of the table grid, then the value shall be ignored and the first cell in the row may span the full table grid (i.e. the second cell, if one exists, should start at the last shared edge in the table).

[*Example*: Consider a table whose second row starts after the first grid unit:

In this table, the second row skips one grid unit at the beginning which is represented by the following WordprocessingML:

```
<w:tr>
  <w:trPr>
    <w:gridBefore w:val="1" />
    …
  </w:trPr>
  …
</w:tr>
```

end example]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element. [*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.4.12 gridCol (Grid Column Definition)

This element specifies the presence and details about a single grid column within a table grid. A *grid column* is a logical column in a table used to specify the presence of a shared vertical edge in the table. When table cells are then added to this table, these shared edges (or grid columns, looking at the column between those shared edges) determine how table cells are placed into the table grid.

[*Example*: If a table row specifies that it is preceded by two grid columns, then it would start on the third vertical edge in the table including edges which are not shared by all columns. *end example*]

If the table grid does not match the requirements of one or more rows in the table (i.e. it does not define enough grid columns), then the grid may be redefined as needed when the table is processed.

[*Example*: Consider the following, more complex table that has two rows and two columns; as shown, the columns are not aligned:

This table is represented by laying out the cells on a table grid consisting of three table grid columns as follows, each grid column representing a logical vertical column in the table:

The dashed lines represent the virtual vertical continuations of each table grid column, and thus resulting table grid is represented as the following in WordprocessingML:

```
<w:tblGrid>
  <w:gridCol w:w="5051" />
  <w:gridCol w:w="3008" />
  <w:gridCol w:w="1531" />
</w:tblGrid>
```

end example]

Parent Elements
tblGrid (§2.4.44); tblGrid (§2.4.45)

Attributes	Description
w (Grid Column Width)	Specifies the width of this grid column. [*Note*: This value does not solely determine the actual width of the resulting grid column in the document. When the table is displayed in a document, these widths determine the initial width of each grid column, which may then be overridden by: • The table layout algorithm (§2.4.49;§2.4.50) applied to the current table row(s) • The preferred widths of specific cells which are part of that grid column as the table is displayed (which is an input to the algorithm above) *end note*] This value is specified in twentieths of a point.

Attributes	Description

	If this attribute is omitted, then the last saved width of the grid column is assumed to be zero.
	
	[*Example*: Consider the following table grid definition:
	
	`<w:tblGrid>`
	`  <w:gridCol w:w="6888"/>`
	`  <w:gridCol w:w="248"/>`
	`  <w:gridCol w:w="886"/>`
	`  <w:gridCol w:w="1554"/>`
	`</w:tblGrid>`
	
	This table grid specifies four grid columns, each of which has an initial size of 6888 twentieths of a point, 248 twentieths of a point, 886 twentieths of a point, and 1554 twentieths of a point respectively. *end example*]
	
	The possible values for this attribute are defined by the ST_TwipsMeasure simple type (§2.18.105).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblGridCol">
    <attribute name="w" type="ST_TwipsMeasure"/>
</complexType>
```

2.4.13 gridSpan (Grid Columns Spanned by Current Table Cell)

This element specifies the number of grid columns in the parent table's table grid which shall be spanned by the current cell. This property allows cells to have the appearance of being merged, as they span vertical boundaries of other cells in the table.

If this element is omitted, then the number of grid units spanned by this cell shall be assumed to be one. If the number of grid units specified by the val attribute exceeds the size of the table grid, then the table grid shall be augmented as needed to create the number of grid columns required.

[*Example*: Consider the following table that has two rows and two columns where the columns are not aligned:

This table is represented by laying out the cells on a table grid consisting of three table grid columns, each grid column representing a logical vertical column in the table:

The first table cell in the first row spans two grid column units. The second cell in the second row also consumes two grid column units (see the grid lines represented using dotted lines in the example above). This table is represented using the following WordprocessingML:

```
<w:tbl>
  …
  <w:tr>
    <w:tc>
      <w:tcPr>
        …
        <w:gridSpan w:val="2" />
      </w:tcPr>
      …
    </w:tc>
    …
  </w:tr>
  <w:tr>
    <w:tc>
      …
    </w:tc>
    <w:tc>
      <w:tcPr>
        …
        <w:gridSpan w:val="2" />
      </w:tcPr>
      …
    </w:tc>
  </w:tr>
</w:tbl>
```

The gridSpan element indicates the number of columns spanned by each cell with respect to the table grid (in the case of R1C1 and TR2C2, two. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description
val (Decimal Number Value)	Specifies that the contents of this attribute will contain a decimal number. The contents of this decimal number are interpreted based on the context of the parent XML element.

Attributes	Description
	[*Example*: Consider the following numeric WordprocessingML property of type ST_DecimalNumber: <w:… w:val="1512645511" /> The value of the val attribute is a decimal number whose value must be interpreted in the context of the parent element. *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_DecimalNumber">
   <attribute name="val" type="ST_DecimalNumber" use="required"/>
</complexType>
```

2.4.14 hidden (Hidden Table Row Marker)

This element specifies that the glyph representing the end character of current table row shall not be displayed in the current document.

[*Note*: This setting is used to hide the end of row glyph in order to ensure that the entire table row is hidden and not displayed in the document, as if any part of the row is visible, the row is displayed. *end note*]

[*Note*: Applications may have settings which allow hidden content to be displayed, in which case this content may be visible - this property is not meant to supersede that setting. *end note*]

If this element is omitted, then this table row shall not be hidden in the document.

[*Example*: Consider a table with a table row in which the row is specified to be hidden. That requirement is specified using the following WordprocessingML:

```
<w:tbl>
  …
  <w:tr>
    <w:trPr>
      <w:hidden />
      …
    </w:trPr>
    …
  </w:tr>
</w:tbl>
```

In this example this row will not be displayed nor printed, as the hidden element is specified on in table row's properties. *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.4.15 hideMark (Ignore End Of Cell Marker In Row Height Calculation)

This element specifies whether the end of cell glyph shall influence the height of the given table row in the table. If it is specified, then only printing characters in this cell shall be used to determine the row height.

[*Rationale*: Typically, the height of a table row is determined by the height of all glyphs in all cells in that row, including the non-printing end of cell glyph characters. However, if these characters are not formatted, they are always created with the document default style properties. This means that the height of a table row cannot ever be reduced below the size of the end of cell marker glyph without manually formatting each paragraph in that run.

In a typical document, this behavior is desirable as it prevents table rows from 'disappearing' if they have no content. However, if a table row is being used as a border (for example, by shading its cells or putting an image in them), then this behavior makes it impossible to have a virtual border that is reasonably small without formatting each cell's content directly. This setting specifies that the end of cell glyph shall be ignored for this cell, allowing it to collapse to the height of its contents without formatting each cell's end of cell marker, which would have the side effect of formatting any text ever entered into that cell. *end rationale*]

If this element is omitted, then the end of cell marker shall be included in the determination of the height of this row.

[*Example*: Consider the following WordprocessingML table:

Here is some small text.			

Notice that the only printing content in this table row is displayed using 5 point font, yet the row height is influenced by the end of cell markers in the empty cells.

If each cell in the second row in this table was set to exclude the table cell from this calculation, using the following WordprocessingML:

```
<w:tcPr>
  <w:hideMark/>
</w:tcPr>
```

The resulting table shall exclude the cell markers from the row height calculation:

Here is some text.			

The hideMark element specified that each cell marker was excluded, resulting in the row height being defined by the actual run contents. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.4.16 hMerge (Horizontally Merged Cell)

This element specifies that this cell is part of a horizontally merged set of cells in a table. The val attribute on this element determines how this cell is defined with respect to the previous cell in the table (i.e. does this cell continue the horizontal merge or start a new merged group of cells).

[*Note*: This property is maintained for compatibility with legacy word processing documents which defined tables in this manner. Whenever possible, this form or horizontal merges should not be produced, and should be translated to the appropriate gridSpan (§2.4.13) settings on the table cells instead. *end note*]

If this element is omitted, then this cell shall not be part of any horizontally merged grouping of cells, and any horizontal merge group in the preceding cells shall be closed.

[*Example*: Consider a table with one row and three columns with the last two columns horizontally merged:

The second cell in the first row starts a merge that is completed in the right adjacent cell, resulting in the following WordprocessingML:

```
<w:tbl>
   …
  <w:tr>
     <w:tc>
       …
    </w:tc>
     <w:tc>
       <w:tcPr>
         <w:hmerge w:val="restart"/>
      </w:tcPr>
      …
    </w:tc>
    <w:tc>
      <w:tcPr>
        <w:hmerge/>
      </w:tcPr>
      …
    </w:tc>
  </w:tr>
</w:tbl>
```

The hmerge element defines the cells which are horizontally merged, and how each group is merged together. *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description

val (Horizontal Merge Type)	Specifies how the table cell is part of a horizontally merged region. This determine whether the cell should join onto an existing grouping of merged cells if any exist, or start a new group of merged cells. Refer to the simple type definition for a full description of each type.
	
	If this attribute is omitted, its value shall be assumed to be `continue`.
	
	[*Example*: Consider a table cell where a horizontal cell merge begins represented as the following WordprocessingML:
	
	`<w:tcPr>`
	`  <w:hmerge w:val="restart"/>`
	`</w:tcPr>`
	
	The attribute value of `restart` specifies that this element shall start a new horizontally merged region in this table. *end example*]
	
	The possible values for this attribute are defined by the ST_Merge simple type (§2.18.64).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_HMerge">
   <attribute name="val" type="ST_Merge"/>
</complexType>
```

2.4.17 insideH (Table Inside Horizontal Edges Border)

This element specifies the border which shall be displayed on all horizontal table cell borders which are not on an outmost edge of the parent table (all horizontal borders which are not the topmost or bottommost border). The appearance of this table cell border in the document shall be determined by the following settings:

- The display of the border on interior edges is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the inside horizontal borders of this table shall have the border specified by the associated table style. If no inside horizontal edge border is specified in the style hierarchy, then this table shall not have an inside horizontal edge border.

[*Example*: Consider a table in which the table specifies a border on all interior horizontal and vertical edges, as follows:

R1C1	R1C2
R2C1	R2C2

This interior horizontal cell border is specified using the following WordprocessingML:

```
<w:tblPr>
  <w:tblBorders>
    <w:insideH w:val="doubleWave" w:sz="6" w:space="0" w:color="92D050"/>
    <w:insideV w:val="doubleWave" w:sz="6" w:space="0" w:color="92D050"/>
  </w:tblBorders>
  …
</w:tblPr>
```

The insideH element specifies a ¾ point border of type doubleWave. *end example*]

Parent Elements
tblBorders (§2.4.37); tblBorders (§2.4.38)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: <w:bottom … w:color="auto"/> This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest

Attributes	Description
	from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points. [*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows: `<w:pgBorders w:offsetFrom="page">`

Attributes	Description
	<w:bottom … w:space="24/> </w:pgBorders> The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*] The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).
sz (Border Width)	Specifies the width of the current border. If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value. If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value. [*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup: <w:top w:val="dashed" w:sz="24" …/> <w:left w:val="dashed" w:sz="24" …/> <w:bottom w:val="dashed" w:sz="24" …/> <w:right w:val="dashed" w:sz="24" …/> The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).
themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup: <w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2"

Attributes	Description
	w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get:

Attributes	Description
	$$L^{'} = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}^{'} = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD.

Attributes	Description
	The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L' = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.18 insideH (Table Cell Inside Horizontal Edges Border)

This element specifies the border which shall be displayed on all interior horizontal edges of the current group of table cells. [*Note*: Although individual table cells have no concept of an internal edge, which would render this property useless in most cases, it is used to determine the cell borders to apply to a specific group of cells as part of table conditional formatting in a table style, for example, the inside horizontal edges on the set of cells in the first column. *end note*]

The appearance of this table cell border in the document shall be determined by the following settings:

- If the net tblCellSpacing element value (§2.4.41;§2.4.42;§2.4.43) applied to the cell is non-zero, then the cell border shall always be displayed
- Otherwise, the display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the specified conditional formatting on the table shall not change the current set of internal edge borders on its set of table cells (i.e. their current setting shall remain unchanged).

[*Example*: Consider a table in which the conditional formatting on the first column specified in the associated table style specifies a double line red cell border for all internal horizontal lines as follows:

R1C1	R1C2
R2C1	R2C2

This inner horizontal edge cell border is specified using the following WordprocessingML:

```
<w:tblStylePr w:type="firstColumn">
  <w:tcPr>
    <w:tcBorders>
      <w:insideH w:val="double" w:sz="4" w:space="0" w:color="FF0000"/>
    </w:tcBorders>
  </w:tcPr>
</w:tblStylePr>
```

The insideH element specifies a ¼ point border of type double. *end example*]

Parent Elements
tcBorders (§2.4.63)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a

Attributes	Description
	consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border.

Attributes	Description
	end example] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of text in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`

Attributes	Description
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).
themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup: `<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />` The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$

Attributes	Description
	The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * Shade_{percentage}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows:

Attributes	Description
	$$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML:

Attributes	Description
	<w:left w:val="single" …/> This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.19 insideV (Table Cell Inside Vertical Edges Border)

This element specifies the border which shall be displayed on all interior vertical edges of the current group of table cells. [*Note*: Although individual table cells have no concept of an internal edge, which would render this property useless in most cases, it is used to determine the cell borders to apply to a specific group of cells as part of table conditional formatting in a table style, for example, the inside vertical edges on the set of cells in the header row. *end note*]

The appearance of this table cell border in the document shall be determined by the following settings:

- If the net tblCellSpacing element value (§2.4.41;§2.4.42;§2.4.43) applied to the cell is non-zero, then the cell border shall always be displayed
- Otherwise, the display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the specified conditional formatting on the table shall not change the current set of internal edge borders on its set of table cells (i.e. their current setting shall remain unchanged).

[*Example*: Consider a table in which the conditional formatting on the header row in the associated table style specifies a double line red cell border for all internal vertical lines as follows:

R1C1	R1C2
R2C1	R2C2

This inner vertical edge cell border is specified using the following WordprocessingML:

```
<w:tblStylePr w:type="firstRow">
  <w:tcPr>
    <w:tcBorders>
      <w:insideV w:val="double" w:sz="4" w:space="0" w:color="FF0000"/>
    </w:tcBorders>
  </w:tcPr>
</w:tblStylePr>
```

The insideV element specifies a ¼ point border of type double. *end example*]

Parent Elements
tcBorders (§2.4.63)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is true, indicating that the border frame effect shall be applied. *end*

Attributes	Description
	example] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.

Attributes	Description

	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2"`
	`w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75 = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$ and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2"`

Attributes	Description
	`w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`.

Attributes	Description
	This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.20 insideV (Table Inside Vertical Edges Border)

This element specifies the border which shall be displayed on all vertical table cell borders which are not on an outmost edge of the parent table (all horizontal borders which are not the leftmost or rightmost border). The appearance of this table cell border in the document shall be determined by the following settings:

- The display of the border on interior edges is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the inside vertical borders of this table shall have the border specified by the associated table style. If no inside vertical edge border is specified in the style hierarchy, then those cells in this table shall not have an inside vertical edge border.

[*Example*: Consider a table in which the table specifies a border on all interior horizontal and vertical edges, as follows:

R1C1	R1C2
R2C1	R2C2

This interior horizontal cell border is specified using the following WordprocessingML:

```
<w:tblPr>
  <w:tblBorders>
    <w:insideH w:val="doubleWave" w:sz="6" w:space="0" w:color="92D050"/>
    <w:insideV w:val="doubleWave" w:sz="6" w:space="0" w:color="92D050"/>
  </w:tblBorders>
  …
</w:tblPr>
```

The insideV element specifies a ¾ point border of type doubleWave on all interior vertical edges. *end example*]

Parent Elements
tblBorders (§2.4.37); tblBorders (§2.4.38)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value.

Attributes	Description
	The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.

Attributes	Description

	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:

Attributes	Description
	<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D.

Attributes	Description
	The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L^{'} = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $T_{xml} = 0.6 * 255$ $= 153$ $= 99(hex)$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}^{'} = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$ • Convert the resultant HSL color to RGB

Attributes	Description
	[*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L' = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.21 jc (Table Alignment Exception)

This element specifies the alignment of the set of rows which are part of the current table properties exception list with respect to the text margins in the current section. When a table is placed in a WordprocessingML document that does not have the same width as the margins, this property is used to determine how the table is positioned with respect to those margins. The interpretation of property is reversed if the parent table is right to left using the bidiVisual element (§2.4.1).

If this property is omitted on a table, then the justification shall be determined by the default set of table properties on the parent table.

[*Example*: Consider the following WordprocessingML table, centered on the text margins with a subset of its rows justified to the left margin by a table property exception:

That exception would be specified using the following WordprocessingML:

```
<w:tblPrEx>
  <w:jc w:val="left"/>
</w:tblPrEx>
```

The jc element specifies that the rows which are part of the table properties exception table shall be `left` aligned with respect to the text margins. *end example*]

Parent Elements
tblPrEx (§2.4.57); tblPrEx (§2.4.58)

Attributes	Description

val (Alignment Type)	Specifies the justification which should be applied to the parent object within a document.
	
	The possible values (see below) for this attribute are always specified relative to the page, and do not change semantic from right-to-left and left-to-right documents.
	
	[*Example*: Consider the following WordprocessingML fragment for a paragraph in a document:
	
	`<w:pPr>`
	`  <w:jc w:val="right" />`
	`</w:pPr>`
	
	This paragraph is now right justified on the page, regardless of the paragraph or section settings. *end example*]
	
	The possible values for this attribute are defined by the ST_Jc simple type (§2.18.50).

The following XML Schema fragment defines the contents of this element:

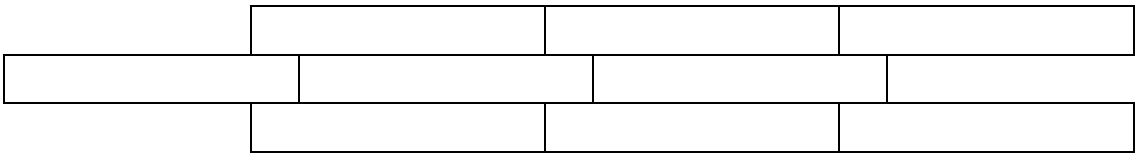
```
<complexType name="CT_Jc">
   <attribute name="val" type="ST_Jc" use="required"/>
</complexType>
```

2.4.22 jc (Table Row Alignment)

This element specifies the alignment of a single row in the parent table with respect to the text margins in the current section. When a table is placed in a WordprocessingML document that does not have the same width as the margins, this property is used to determine how a specific row in that table is positioned with respect to those margins. The interpretation of property is reversed if the parent table is right to left using the bidiVisual element (§2.4.1).

If this property is omitted on a table, then the justification shall be determined by the default set of table properties on the parent table.

[*Example*: Consider the following WordprocessingML table, centered on the text margins with its second rows justified to the left margin by a table row level justification:



That row level setting would be specified using the following WordprocessingML:

```
<w:trPr>
  <w:jc w:val="left"/>
</w:trPr>
```

The jc element specifies that the rows which are part of the table properties exception table shall be `left` aligned with respect to the text margins. *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description

val (Alignment Type)	Specifies the justification which should be applied to the parent object within a document.
	
	The possible values (see below) for this attribute are always specified relative to the page, and do not change semantic from right-to-left and left-to-right documents.
	
	[*Example*: Consider the following WordprocessingML fragment for a paragraph in a document:
	
	`<w:pPr>`
	`  <w:jc w:val="right" />`
	`</w:pPr>`
	
	This paragraph is now right justified on the page, regardless of the paragraph or section settings. *end example*]
	
	The possible values for this attribute are defined by the ST_Jc simple type (§2.18.50).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Jc">
   <attribute name="val" type="ST_Jc" use="required"/>
</complexType>
```

2.4.23 jc (Table Alignment)

This element specifies the alignment of the current table with respect to the text margins in the current section. When a table is placed in a WordprocessingML document that does not have the same width as the margins, this property is used to determine how the table is positioned with respect to those margins. The interpretation of property is reversed if the parent table is right to left using the bidiVisual element (§2.4.1).

If this property is omitted on a table, then the justification shall be determined by the associated table style. If this property is not specified in the style hierarchy, then the table shall be left justified with zero indentation from the leading margin (the left margin in a left-to-right table or the right margin in a right-to-left table).

[*Example*: Consider the following WordprocessingML table, justified to the left margin by default:

R1C1	R1C2	R1C3
R2C1	R2C2	R2C3

This table does not fill the entire width of the text margins. If the table should be right justified to the margin, as follows:

R1C1	R1C2	R1C3
R2C1	R2C2	R2C3

That requirement would be specified using the following WordprocessingML:

```
<w:tblPr>
  <w:jc w:val="right"/>
</w:tblPr>
```

The jc element specifies that the table shall be `right` aligned with respect to the text margins. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description

val (Alignment Type)	Specifies the justification which should be applied to the parent object within a document.
	
	The possible values (see below) for this attribute are always specified relative to the page, and do not change semantic from right-to-left and left-to-right documents.
	
	[*Example*: Consider the following WordprocessingML fragment for a paragraph in a document:
	
	`<w:pPr>`
	`  <w:jc w:val="right" />`
	`</w:pPr>`
	
	This paragraph is now right justified on the page, regardless of the paragraph or section settings. *end example*]
	
	The possible values for this attribute are defined by the ST_Jc simple type (§2.18.50).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Jc">
   <attribute name="val" type="ST_Jc" use="required"/>
</complexType>
```

2.4.24 left (Table Cell Left Border)

This element specifies the border which shall be displayed on the left side of the current table cell. The appearance of this table cell border in the document shall be determined by the following settings:

- If the net tblCellSpacing element value (§2.4.41;§2.4.42;§2.4.43) applied to the cell is non-zero, then the cell border shall always be displayed
- Otherwise, the display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the left side of this table cell shall not have a cell border, and its border may use the table's border settings as appropriate.

[*Example*: Consider a table in which the second cell in the first row specifies a left cell border

R1C1	R1C2
R2C1	R2C2

This left cell border is specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    …
    <w:tcBorders>
      <w:left w:val="double" w:sz="4" w:space="0" w:color="FF0000" />
    </w:tcBorders>
  </w:tcPr>
  <w:p/>
</w:tc>
```

The left element specifies a ½ point border of type double on the table cell. *end example*]

Parent Elements
tcBorders (§2.4.63)

Attributes	Description
color (Border Color)	Specifies the color for this border.

Attributes	Description
	This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value auto, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is true, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />`

Attributes	Description
	This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object.
	
	When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`

Attributes	Description
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*] The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$

Attributes	Description
	The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * Shade_{percentage}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows:

Attributes	Description
	$$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML:

Attributes	Description
	<w:left w:val="single" …/> This border's val is single, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.25 left (Table Cell Left Margin Exception)

This element specifies the amount of space which shall be left between the left extent of the current cell contents and the left border of a specific individual table cell within a table. This setting shall override the table cell bottom margin definition specified by the left element contained within the table properties (§2.4.26).

This value is specified in the units applied via its type attribute. Any width value of type pct or auto for this element shall be ignored.

If omitted, then this table cell shall use the bottom cell margins defined in the left element contained within the table properties (§2.4.26).

[*Example*: Consider a two row, two column table in which the first table cell in the second row has a left margin which is specified via an exception to be 0.5 inches, causing the text to be position 0.5" inside the cell, as follows:

R1C1	R1C2
R2C1	R2C2

The exception on this cell would be specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    <w:tcMar>
      <w:left w:w="720" w:type="dxa" />
    </w:tcMar>
  </w:tcPr>
</w:tc>
```

The R2C1 cell in this table has an exception applied to the table cell left cell margin setting it to 720 twentieths of a point (0.5 inches). *end example*]

Parent Elements
tcMar (§2.4.65)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches).

Attributes	Description
	end example] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.26 left (Table Cell Left Margin Default)

This element specifies the amount of space which shall be left between the left extent of the cell contents and the left border of all table cells within the parent table (or table row). This setting may be overridden by the table cell bottom margin definition specified by the left element contained within the table cell's properties (§2.4.26).

This value is specified in the units applied via its type attribute. Any width value of type `pct` or `auto` for this element shall be ignored.

If this element is omitted, then it shall inherit the table cell margin from the associated table style. If a left margin is never specified in the style hierarchy, this table shall have 115 twentieths of a point (0.08 inches) left cell padding by default (excepting individual cell overrides).

[*Example*: Consider a two by two table in which the default table cell left margin is specified to be exactly 0.25 inches, as follows (marked with an arrow in the first table cell below):

↔ R1C1	R2C1
R2C1	R2C2

This table property is specified using the following WordprocessingML markup:

```
<w:tbl>
  <w:tblPr>
    <w:tblCellMar>
      <w:left w:w="360" w:type="dxa"/>
    </w:tblCellMar>
  </w:tblPr>
  …
</w:tbl>
```

Every cell in the table has a default left cell margin setting it to `360` twentieths of a point. *end example*]

Parent Elements
tblCellMar (§2.4.39); tblCellMar (§2.4.40)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.27 left (Table Left Border)

This element specifies the border which shall be displayed at the left edge of the current table. The appearance of this table border in the document shall be determined by the following settings:

- The display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the left edge of this table shall have the border specified by the associated table style. If no left border is specified in the style hierarchy, then this table shall not have a left border.

[*Example*: Consider a table in which the table properties specify a left table border, as follows:

R1C1	R1C2
R2C1	R2C2

This left table border is specified using the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblBorders>
      <w:left w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="D0D0D0" w:themeColor="accent3" w:themeTint="99"/>
    </w:tblBorders>
  </w:tblPr>
  …
</w:tbl>
```

The left element specifies a three point left table border of type `thinThinThickMediumGap`. *end example*]

Parent Elements
tblBorders (§2.4.37); tblBorders (§2.4.38)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for

Attributes	Description
	example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance

Attributes	Description

	between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (`dashed`), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor	Specifies a theme color to be applied to the current border.

Attributes	Description

(Border Theme Color)	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows:

Attributes	Description
	$$L^{'} = L * Shade_{percentage}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `C0504D`. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L^{'} = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get `943634`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied

Attributes	Description
	as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * Tint_{pct} + (1 - Tint_{pct})$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
   <attribute name="val" type="ST_Border" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
   <attribute name="space" type="ST_PointMeasure" use="optional"/>
   <attribute name="shadow" type="ST_OnOff" use="optional"/>
   <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.28 noWrap (Don't Wrap Cell Content)

This element specifies how this table cell shall be laid out when the parent table is displayed in a document. This setting only affects the behavior of the cell when the tblLayout for this row (§2.4.49; §2.4.50) is set to use the auto algorithm.

This setting shall be interpreted in the context of the tcW element (§2.4.68) as follows:

- If the table cell width has a type attribute value of fixed, then this element specifies that that this table cell shall never be smaller than that fixed value when other cells on the line are not at their absolute minimum width.
- If the table cell width has a type attribute value of pct or auto, then this element specifies that when running the auto fit algorithm, the contents of that this table cell shall be treated as though they have no breaking characters (the contents should be treated as a single contiguous non-breaking string)

If this element is omitted, then cell content shall be allowed to wrap (the cell may be shrunk as needed if it is a fixed preferred width value, and the contents shall be treated as having breaking characters if it is a percentage or automatic width value).

[*Example*: Consider the following three row by three column WordprocessingML table:

In this table, each cell has a fixed preferred width of 2.38 inches (3427 twentieths of a point), and the tblLayout for this row (§2.4.49; §2.4.50) is set to use the auto algorithm. If a long non breaking string is added to the middle row, as follows, the two cells are adjusted to override their preferences and accommodate the string:

	sssssssssssssssssssssssssssssssssssssssssssssssssssssssssssssssss	

However, if the first table cell has the noWrap element present as follows:

```
<w:tcPr>
  <w:noWrap/>
</w:tcPr>
```

The noWrap element specifies that because it is a fixed width cell, that cell shall not be collapsed beyond its original size until all other cells are at their minimum size, so in this example the cell maintains its width:

	sssssssssssssssssssssssssssssssssssssssssssssssssssssssssssssssss	

end example]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description
val (On/Off Value)	Specifies a binary value for the property defined by the parent XML element. A value of on, 1, or true specifies that the property shall be explicitly applied. This is the default value for this attribute, and is implied when the parent element is present, but this attribute is omitted. A value of off, 0, or false specifies that the property shall be explicitly turned off. [*Example*: For example, consider the following on/off property: `<w:… w:val="off"/>` The val attribute explicitly declares that the property is turned off. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_OnOff">
   <attribute name="val" type="ST_OnOff"/>
</complexType>
```

2.4.29 right (Table Cell Right Margin Default)

This element specifies the amount of space which shall be present between the right extent of the cell contents and the right border of all table cells within the parent table (or table row). This setting may be overridden by the table cell bottom margin definition specified by the right element contained within the table cell's properties (§2.4.31).

This value is specified in the units applied via its type attribute. Any width value of type `pct` or `auto` for this element shall be ignored.

If this element is omitted, then it shall inherit the table cell margin from the associated table style. If a right margin is never specified in the style hierarchy, this table shall have 115 twentieths of a point (0.08 inches) left cell padding by default (excepting individual cell overrides).

[*Example*: Consider a two by two table in which the default table cell right margin is specified to be exactly 0.25 inches, as follows (marked with an arrow in the first table cell below):

R1C1 ↔	R2C1
R2C1	R2C2

This table property is specified using the following WordprocessingML markup:

```
<w:tbl>
  <w:tblPr>
    <w:tblCellMar>
      <w:right w:w="360" w:type="dxa"/>
    </w:tblCellMar>
  </w:tblPr>
  …
</w:tbl>
```

Every cell in the table has a default right cell margin setting it to `360` twentieths of a point. *end example*]

Parent Elements
tblCellMar (§2.4.39); tblCellMar (§2.4.40)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point).

Attributes	Description
	[*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.30 right (Table Cell Right Border)

This element specifies the border which shall be displayed on the right side of the current table cell. The appearance of this table cell border in the document shall be determined by the following settings:

- If the net tblCellSpacing element value (§2.4.41;§2.4.42;§2.4.43) applied to the cell is non-zero, then the cell border shall always be displayed
- Otherwise, the display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the right side of this table cell shall not have a cell border, and its border may use the table's border settings as appropriate.

[*Example*: Consider a table in which the second cell in the first row specifies a right cell border as follows:

R1C1	R1C2
R2C1	R2C2

This right cell border is specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    …
    <w:tcBorders>
      <w:right w:val="double" w:sz="4" w:space="0" w:color="FF0000" />
    </w:tcBorders>
  </w:tcPr>
  <w:p/>
</w:tc>
```

The right element specifies a ½ point border of type `double` on the right side of the table cell. *end example*]

Parent Elements
tcBorders (§2.4.63)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value.

Attributes	Description
	The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance between the edge of the page and the beginning of this border in points. When a document has a page border that is relative to the text extents (using a value of `text` in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.

Attributes	Description

	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor (Border Theme Color)	Specifies a theme color to be applied to the current border. The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document. [*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:

Attributes	Description
	<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> <w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" /> The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*] The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D.

Attributes	Description
	The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $L^{'} = 0.53 * 0.75$ $= 0.39698$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $T_{xml} = 0.6 * 255$ $= 153$ $= 99(hex)$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $\mathrm{L}^{'} = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$ • Convert the resultant HSL color to RGB

Attributes	Description
	[*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $L' = 0.53 * 0.6 + (1 - .6)$ $= 0.71$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.31 right (Table Cell Right Margin Exception)

This element specifies the amount of space which shall be present between the right extent of the current cell's text contents and the right border of a specific individual table cell within a table. This setting shall override the table cell bottom margin definition specified by the right element contained within the table properties (§2.4.29).

This value is specified in the units applied via its type attribute. Any width value of type `pct` or `auto` for this element shall be ignored.

If omitted, then this table cell shall use the bottom cell margins defined in the right element contained within the table properties (§2.4.29).

[*Example*: Consider a two row, two column table in which the first table cell in the second row has a right margin which is specified via an exception to be 0.5 inches, the region marked with an arrow in the table below:

R1C1	R1C2
R2C1 ⟷	R2C2

The exception on this cell would be specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    <w:tcMar>
      <w:right w:w="720" w:type="dxa" />
    </w:tcMar>
  </w:tcPr>
  …
</w:tc>
```

The R2C1 cell in this table has an exception applied to the table cell right cell margin setting it to `720` twentieths of a point (0.5 inches). *end example*]

Parent Elements
tcMar (§2.4.65)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.32 right (Table Right Border)

This element specifies the border which shall be displayed at the right edge of the current table. The appearance of this table border in the document shall be determined by the following settings:

- The display of the border is subject to the conflict resolution algorithm defined by the tcBorders element (§2.4.63) and the tblBorders element (§2.4.37;§2.4.38)

If this element is omitted, then the right edge of this table shall have the border specified by the associated table style. If no right border is specified in the style hierarchy, then this table shall not have a right border.

[*Example*: Consider a table in which the table properties specify a right table border, as follows:

R1C1	R1C2
R2C1	R2C2

This right table border is specified using the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblBorders>
      <w:right w:val="thinThickThinMediumGap" w:sz="24" w:space="0"
w:color="D0D0D0" w:themeColor="accent3" w:themeTint="99"/>
    </w:tblBorders>
  </w:tblPr>
  …
</w:tbl>
```

The right element specifies a three point right table border of type `thinThinThickMediumGap`. *end example*]

Parent Elements
tblBorders (§2.4.37); tblBorders (§2.4.38)

Attributes	Description
color (Border Color)	Specifies the color for this border. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the border color as appropriate. [*Example*: Consider a border color with value `auto`, as follows: `<w:bottom … w:color="auto"/>` This color therefore may be automatically be modified by a consumer as appropriate, for

Attributes	Description
	example, in order to ensure that the border can be distinguished against the page's background color. *end example*] If the border style (the val attribute) specifies the use of an art border, this attribute is ignored. As well, if the border specifies the use of a theme color via the themeColor attribute, this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
frame (Create Frame Effect)	Specifies whether the specified border should be modified to create a frame effect by reversing the border's appearance from the edge nearest the text to the edge furthest from the text. If this attribute is omitted, then the border is not given any frame effect. [*Example*: Consider a bottom border which shall appear with a frame effect, which is specified in the following WordprocessingML: `<w:bottom w:frame="true" ... />` This frame's val is `true`, indicating that the border frame effect shall be applied. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
shadow (Border Shadow)	Specifies whether this border should be modified to create the appearance of a shadow. For the right and bottom borders, this is accomplished by duplicating the border below and right of the normal border location. For the right and top borders, this is accomplished by moving the order down and to the right of its original location. If this attribute is omitted, then the border is not given the shadow effect. [*Example*: Consider a top border which shall appear with a shadow effect, resulting in the following WordprocessingML: `<w:bottom w:shadow="true" ... />` This frame's val is `true`, indicating that the shadow effect shall be applied to the border. *end example*] The possible values for this attribute are defined by the ST_OnOff simple type (§2.18.67).
space (Border Spacing Measurement)	Specifies the spacing offset that shall be used to place this border on the parent object. When a document has a page border that is relative to the page edges (using a value of page in the offsetFrom attribute on pgBorders (§2.6.10)), it shall specify the distance

Attributes	Description

	between the edge of the page and the beginning of this border in points.
	
	When a document has a page border that is relative to the text extents (using a value of text in the offsetFrom attribute on pgBorders (§2.6.10)), or any other border type, it shall specify the distance between the edge of the object and the beginning of this border in points.
	
	[*Example*: Consider a document with a set of page borders all specified to appear 24 points from the edge of the page. The resulting WordprocessingML would be as follows:
	
	`<w:pgBorders w:offsetFrom="page">`
	`  <w:bottom … w:space="24/>`
	`</w:pgBorders`
	
	The offsetFrom attribute specifies that the space value will provide the offset of the page border from the page edge, and the value of the space attribute specifies that the page offset shall be 24 points. *end example*]
	
	The possible values for this attribute are defined by the ST_PointMeasure simple type (§2.18.75).

sz (Border Width)	Specifies the width of the current border.
	
	If the border style (val attribute) specifies a line border, the width of this border is specified in measurements of eighths of a point, with a minimum value of two (one-fourth of a point) and a maximum value of 96 (twelve points). Any values outside this range may be reassigned to a more appropriate value.
	
	If the border style (val attribute) specifies an art border, the width of this border is specified in measurements of points, with a minimum value of one and a maximum value of 31. Any values outside this range may be reassigned to a more appropriate value.
	
	[*Example*: Consider a document with a three point wide dashed line border on all sides, resulting in the following WordprocessingML markup:
	
	`<w:top w:val="dashed" w:sz="24" …/>`
	`<w:left w:val="dashed" w:sz="24" …/>`
	`<w:bottom w:val="dashed" w:sz="24" …/>`
	`<w:right w:val="dashed" w:sz="24" …/>`
	
	The border style is specified using the val attribute, and because that border style is a line border (dashed), the sz attribute specifies the size in eighths of a point (24 eighths of a point = 3 points). *end example*]
	
	The possible values for this attribute are defined by the ST_EighthPointMeasure simple type (§2.18.27).

themeColor	Specifies a theme color to be applied to the current border.

Attributes	Description

(Border Theme Color)	The specified theme color is a reference to one of the predefined theme colors, located in the document's Theme part,which allows color information to be set centrally in the document.
	
	[*Example*: Consider a set of borders configured to use the accent2 theme color, resulting in the following WordprocessingML markup:
	
	`<w:top … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:bottom … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:left … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	`<w:right … w:color="FFA8A0" w:themeColor="accent2" w:themeTint="99" />`
	
	The borders have a color with an RGB value of FFA8A0, however, because the themeColor attribute is specified, that value is ignored in favor of the accent2 theme color specified for this document. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeShade (Border Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this border instance. If the themeShade is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0–255) applied to the current border. [*Example*: Consider a shade of 40% applied to a border in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows:

Attributes	Description
	$$L^{'} = L * Shade_{percentage}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `C0504D`. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L^{'} = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get `943634`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="943634" w:themeColor="accent2" w:themeShade="BF"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Border Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this border instance. If the themeTint is supplied, then it is applied to the RGB value of the theme color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0–255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied

Attributes	Description
	as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the `accent2` theme color, whose RGB value (in RRGGBB hex format) is `4F81BD`. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get `95B3D7`. This transformed value can be seen in the resulting background's color attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:color="95B3D7" w:themeColor="accent2" w:themeTint="99"/>` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Border Style)	Specifies the style of border used on this object. This border can either be an art border (a repeated image along the borders - only valid for page borders) or a line border (a line format repeated along the borders) - see the simple type definition for a description of each border style. [*Example*: Consider a left border resulting in the following WordprocessingML: `<w:left w:val="single" …/>` This border's val is `single`, indicating that the border style is a single line. *end example*] The possible values for this attribute are defined by the ST_Border simple type (§2.18.4).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Border">
    <attribute name="val" type="ST_Border" use="required"/>
    <attribute name="color" type="ST_HexColor" use="optional"/>
    <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
    <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
    <attribute name="sz" type="ST_EighthPointMeasure" use="optional"/>
    <attribute name="space" type="ST_PointMeasure" use="optional"/>
    <attribute name="shadow" type="ST_OnOff" use="optional"/>
    <attribute name="frame" type="ST_OnOff" use="optional"/>
</complexType>
```

2.4.33 shd (Table Cell Shading)

This element specifies the shading which shall be applied to the extents of the current table cell. Similarly to paragraph shading, this shading shall be applied to the contents of the cell up to the cell borders, regardless of the presence of text.

This shading consists of three components:

- Background Color
- (optional) Pattern
- (optional) Pattern Color

The resulting shading is applied by setting the background color behind the paragraph, then applying the pattern color using the mask supplied by the pattern over that background.

If this element is omitted, then the cell shading shall be determined by the table-level or table-level exception cell shading settings (§2.4.34;§2.4.35) for the current table.

[*Example*: Consider a table in which the first cell in the first row has cell-level red shading, as follows:

R1C1	R1C2
R2C1	R2C2

This cell shading would be specified using the following WordprocessingML:

```
<w:tc>
  <w:tcPr>
    <w:shd w:val="clear" w:color="auto" w:fill="FF0000" />
  </w:tcPr>
</w:tc>
```

The shd element specifies cell shading with a `clear` pattern using a background color of `FF0000` (red). *end example*]

Parent Elements
tcPr (§2.7.5.8); tcPr (§2.4.66); tcPr (§2.7.5.9); tcPr (§2.4.67)

Attributes	Description
color (Shading Pattern Color)	Specifies the color used for any foreground pattern specified for this shading using the val attribute. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the foreground shading color as appropriate. If the shading style (the val attribute) specifies the use of no shading format or is omitted, then this property has no effect. Also, if the shading specifies the use of a theme color via the themeColor attribute, then this value is superseded by the theme color value. If this attribute is omitted, then its value shall be assumed to be auto. [*Example*: Consider a shading of type pct20 with a foreground color value of auto, as follows: `<w:shd w:val="pct20"... w:color="auto"/>` The foreground color for this shading pattern therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the shading color can be distinguished against the page's background color. *end example*] The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
fill (Shading Background Color)	Specifies the color used for the background for this shading. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the background shading color as appropriate. If this attribute is omitted, then its value shall be assumed to be auto. [*Example*: Consider a shading using a background color of hex value C3D69B, using the following WordprocessingML: `<w:shd w:fill="C3D69B" />` The background color for this shading therefore will be a color with a hex value of C3D69B. *end example*] If the shading specifies the use of a theme color via the themeFill attribute, then this value is superseded by the theme color value.

Attributes	Description
	The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).

themeColor (Shading Pattern Theme Color)	Specifies a theme color which should be applied to any foreground pattern specified for this shading using the val attribute.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document.
	
	If this element is omitted, then no theme color is applied, and the color attribute shall be used to determine the shading pattern color.
	
	[*Example*: Consider a paragraph which shall have a background consisting of a theme color `accent3` with a theme color `accent6` overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:shd w:val="pct20" w:themeColor="accent6"`
	`w:themeFill="accent3" />`
	`</w:pPr>`
	
	The resulting paragraph will use the foreground pattern color `accent6` in the region specified by the `pct20` pattern mask. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeFill (Shading Background Theme Color)	Specifies a theme color which should be applied to the background for this shading.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document.
	
	If this element is omitted, then no theme color is applied, and the color attribute shall be used to determine the shading background color.
	
	[*Example*: Consider a paragraph which shall have a background consisting of a theme color `accent3` with a theme color `accent6` overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:
	
	`<w:shd w:val="pct20" w:themeColor="accent6"`
	`w:themeFill="accent3" />`
	
	The resulting shading will use the background color specified by the `accent3` theme color. *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).
themeFillShade (Shading Background Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this shading color. If the themeFillShade is supplied, then it is applied to the RGB value of the themeFill color (from the theme part) to determine the final color applied to this border. The themeFillShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeFillShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75 = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$ and converting back to RGB, we get 943634. This transformed value can be seen in the resulting shading's fill attribute: `<w:shd w:fill="943634" w:themeFill="accent2" w:themeFillShade="BF" />`

Attributes	Description
	end example] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeFillTint (Shading Background Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeFillTint is supplied, then it is applied to the RGB value of the themeFill color (from the theme part) to determine the final color applied to this border. The themeFillTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeFillTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting shading's fill attribute:

Attributes	Description
	<w:top w:val="single" w:sz="4" w:space="24" w:fill="95B3D7" w:themeFillColor="accent2" w:themeFillTint="99" /> *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeShade (Shading Pattern Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this shading color. If the themeShade is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ Te resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75 = 0.39698$$

Attributes	Description
	Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:shd w:color="943634" w:themeColor="accent2" w:themeShade="BF" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Shading Pattern Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeTint is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * \text{Tint}_{pct} + \left(1 - \text{Tint}_{pct}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get:

Attributes	Description
	$$L^{'} = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting shading's color attribute: `<w:shd w:color="95B3D7" w:themeColor="accent2" w:themeTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Shading Pattern)	Specifies the pattern which shall be used to lay the pattern color over the background color for this paragraph shading. This pattern consists of a mask which is applied over the background shading color to get the locations where the pattern color should be shown. Each of these possible masks are shown in the simple type values referenced below. [*Example*: Consider a shaded paragraph which uses a 10 percent foreground fill, resulting in the following WordprocessingML: `<w:shd w:val="pct10" .../>` This shading val is pct10, indicating that the border style is a 10 percent foreground fill mask. *end example*] The possible values for this attribute are defined by the ST_Shd simple type (§2.18.85).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Shd">
   <attribute name="val" type="ST_Shd" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="fill" type="ST_HexColor" use="optional"/>
   <attribute name="themeFill" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeFillTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeFillShade" type="ST_UcharHexNumber" use="optional"/>
</complexType>
```

2.4.34 shd (Table Shading Exception)

This element specifies the shading which shall be applied to all cells in the current row as part of a set of table-level property exceptions. Similarly to paragraph shading, this shading shall be applied to the contents of the tab up to the table borders, regardless of the presence of text - unlike cell shading, table shading shall include any cell padding. This property shall be superseded by any cell-level shading on any cell in this row (§2.4.33).

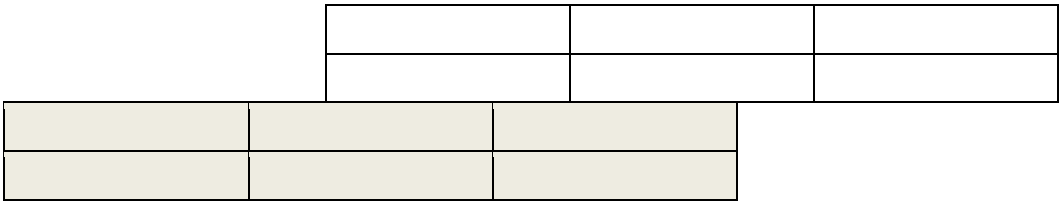
This shading consists of three components:

- Background Color
- (optional) Pattern
- (optional) Pattern Color

The resulting shading is applied by setting the background color behind the paragraph, then applying the pattern color using the mask supplied by the pattern over that background.

If this element is omitted, then the cell shading shall be determined by the table-level cell shading settings (§2.4.35) for the current table.

[*Example*: Consider a table in which the final two rows have a set of table-level property exceptions giving them theme color shading in the `background2` theme color, as follows:



This table-level shading exception would be specified using the following WordprocessingML:

```
<w:tblPrEx>
  <w:jc w:val="left" />
  <w:shd w:val="clear" w:color="auto" w:fill="EEECE1" w:themeFill="background2"
/>
</w:tblPrEx>
```

The shd element specifies cell shading with a `clear` pattern using a background theme color of `background2`. *end example*]

Parent Elements
tblPrEx (§2.4.57); tblPrEx (§2.4.58)

Attributes	Description

Attributes	Description
color (Shading Pattern Color)	Specifies the color used for any foreground pattern specified for this shading using the val attribute. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the foreground shading color as appropriate. If the shading style (the val attribute) specifies the use of no shading format or is omitted, then this property has no effect. Also, if the shading specifies the use of a theme color via the themeColor attribute, then this value is superseded by the theme color value. If this attribute is omitted, then its value shall be assumed to be auto. [*Example*: Consider a shading of type pct20 with a foreground color value of auto, as follows: `<w:shd w:val="pct20"... w:color="auto"/>` The foreground color for this shading pattern therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the shading color can be distinguished against the page's background color. *end example*] The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
fill (Shading Background Color)	Specifies the color used for the background for this shading. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the background shading color as appropriate. If this attribute is omitted, then its value shall be assumed to be auto. [*Example*: Consider a shading using a background color of hex value C3D69B, using the following WordprocessingML: `<w:shd w:fill="C3D69B" />` The background color for this shading therefore will be a color with a hex value of C3D69B. *end example*] If the shading specifies the use of a theme color via the themeFill attribute, then this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
themeColor	Specifies a theme color which should be applied to any foreground pattern specified for

Attributes	Description

(Shading Pattern Theme Color)	this shading using the val attribute.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document.
	
	If this element is omitted, then no theme color is applied, and the color attribute shall be used to determine the shading pattern color.
	
	[*Example*: Consider a paragraph which shall have a background consisting of a theme color `accent3` with a theme color `accent6` overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:shd w:val="pct20" w:themeColor="accent6"`
	`w:themeFill="accent3" />`
	`</w:pPr>`
	
	The resulting paragraph will use the foreground pattern color `accent6` in the region specified by the `pct20` pattern mask. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeFill (Shading Background Theme Color)	Specifies a theme color which should be applied to the background for this shading.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document.
	
	If this element is omitted, then no theme color is applied, and the color attribute shall be used to determine the shading background color.
	
	[*Example*: Consider a paragraph which shall have a background consisting of a theme color `accent3` with a theme color `accent6` overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:
	
	`<w:shd w:val="pct20" w:themeColor="accent6"`
	`w:themeFill="accent3" />`
	
	The resulting shading will use the background color specified by the `accent3` theme color. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeFillShade (Shading	Specifies the shade value applied to the supplied theme color (if any) for this shading color.

Attributes	Description
Background Theme Color Shade)	If the themeFillShade is supplied, then it is applied to the RGB value of the themeFill color (from the theme part) to determine the final color applied to this border. The themeFillShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ The resulting themeFillShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting shading's fill attribute: `<w:shd w:fill="943634" w:themeFill="accent2" w:themeFillShade="BF" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple

Attributes	Description
	type (§2.18.106).
themeFillTint (Shading Background Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeFillTint is supplied, then it is applied to the RGB value of the themeFill color (from the theme part) to determine the final color applied to this border. The themeFillTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeFillTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$ and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting shading's fill attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:fill="95B3D7" w:themeFillColor="accent2" w:themeFillTint="99" />`

Attributes	Description
	end example] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeShade (Shading Pattern Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this shading color. If the themeShade is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ Te resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute:

Attributes	Description
	<w:shd w:color="943634" w:themeColor="accent2" w:themeShade="BF" /> *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Shading Pattern Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeTint is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we

Attributes	Description
	get 95B3D7. This transformed value can be seen in the resulting shading's color attribute: `<w:shd w:color="95B3D7" w:themeColor="accent2" w:themeTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Shading Pattern)	Specifies the pattern which shall be used to lay the pattern color over the background color for this paragraph shading. This pattern consists of a mask which is applied over the background shading color to get the locations where the pattern color should be shown. Each of these possible masks are shown in the simple type values referenced below. [*Example*: Consider a shaded paragraph which uses a 10 percent foreground fill, resulting in the following WordprocessingML: `<w:shd w:val="pct10" .../>` This shading val is `pct10`, indicating that the border style is a 10 percent foreground fill mask. *end example*] The possible values for this attribute are defined by the ST_Shd simple type (§2.18.85).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Shd">
   <attribute name="val" type="ST_Shd" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="fill" type="ST_HexColor" use="optional"/>
   <attribute name="themeFill" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeFillTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeFillShade" type="ST_UcharHexNumber" use="optional"/>
</complexType>
```

2.4.35 shd (Table Shading)

This element specifies the shading which shall be applied to the extents the current table. Similarly to paragraph shading, this shading shall be applied to the contents of the tab up to the table borders, regardless of the presence of text - unlike cell shading, table shading shall include any cell padding. This property shall be

superseded by any cell-level shading via any table-level property exceptions (§2.4.34); or on any cell in this row (§2.4.33).

This shading consists of three components:

- Background Color
- (optional) Pattern
- (optional) Pattern Color

The resulting shading is applied by setting the background color behind the paragraph, then applying the pattern color using the mask supplied by the pattern over that background.

If this element is omitted, then the cells within this table shall have the shading specified by the associated table style. If no cell shading is specified in the style hierarchy, then the cells in this table shall not have any cell shading (i.e. they shall be transparent).

[*Example*: Consider a table in which the first cell in the first row has cell-level red shading, as follows:

R1C1	R1C2
R2C1	R2C2

This table level cell shading would be specified using the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:shd w:val="clear" w:color="auto" w:fill="FF0000"/>
    …
  </w:tblPr>
  …
</w:tbl>
```

The shd element specifies cell shading with a `clear` pattern using a background color of `FF0000` (red). *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Attributes	Description
color (Shading Pattern Color)	Specifies the color used for any foreground pattern specified for this shading using the val attribute. This color may either be presented as a hex value (in RRGGBB format), or `auto` to allow a consumer to automatically determine the foreground shading color as appropriate.

Attributes	Description
	If the shading style (the val attribute) specifies the use of no shading format or is omitted, then this property has no effect. Also, if the shading specifies the use of a theme color via the themeColor attribute, then this value is superseded by the theme color value. If this attribute is omitted, then its value shall be assumed to be auto. [*Example*: Consider a shading of type pct20 with a foreground color value of auto, as follows: `<w:shd w:val="pct20"... w:color="auto"/>` The foreground color for this shading pattern therefore may be automatically be modified by a consumer as appropriate, for example, in order to ensure that the shading color can be distinguished against the page's background color. *end example*] The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
fill (Shading Background Color)	Specifies the color used for the background for this shading. This color may either be presented as a hex value (in RRGGBB format), or auto to allow a consumer to automatically determine the background shading color as appropriate. If this attribute is omitted, then its value shall be assumed to be auto. [*Example*: Consider a shading using a background color of hex value C3D69B, using the following WordprocessingML: `<w:shd w:fill="C3D69B" />` The background color for this shading therefore will be a color with a hex value of C3D69B. *end example*] If the shading specifies the use of a theme color via the themeFill attribute, then this value is superseded by the theme color value. The possible values for this attribute are defined by the ST_HexColor simple type (§2.18.43).
themeColor (Shading Pattern Theme Color)	Specifies a theme color which should be applied to any foreground pattern specified for this shading using the val attribute. The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document.

Attributes	Description

	If this element is omitted, then no theme color is applied, and the color attribute shall be used to determine the shading pattern color.
	
	[*Example*: Consider a paragraph which shall have a background consisting of a theme color accent3 with a theme color accent6 overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:
	
	`<w:pPr>`
	`  <w:shd w:val="pct20" w:themeColor="accent6"`
	`w:themeFill="accent3" />`
	`</w:pPr>`
	
	The resulting paragraph will use the foreground pattern color accent6 in the region specified by the pct20 pattern mask. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeFill (Shading Background Theme Color)	Specifies a theme color which should be applied to the background for this shading.
	
	The specified theme color is a reference to one of the predefined theme colors, located in the document's themes part, which allows for color information to be set centrally in the document.
	
	If this element is omitted, then no theme color is applied, and the color attribute shall be used to determine the shading background color.
	
	[*Example*: Consider a paragraph which shall have a background consisting of a theme color accent3 with a theme color accent6 overlaid using a 20% fill pattern. This requirement is specified using the following WordprocessingML:
	
	`<w:shd w:val="pct20" w:themeColor="accent6"`
	`w:themeFill="accent3" />`
	
	The resulting shading will use the background color specified by the accent3 theme color. *end example*]
	
	The possible values for this attribute are defined by the ST_ThemeColor simple type (§2.18.104).

themeFillShade (Shading Background Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this shading color. If the themeFillShade is supplied, then it is applied to the RGB value of the themeFill color (from the theme part) to determine the final color applied to this border. The themeFillShade value is stored as a hex encoding of the shade value (from 0 to 255)

Attributes	Description
	applied to the current border. [*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255 = 102 = 66(hex)$$ The resulting themeFillShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$L' = L * Shade_{percentage}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75 = 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$ and converting back to RGB, we get 943634. This transformed value can be seen in the resulting shading's fill attribute: `<w:shd w:fill="943634" w:themeFill="accent2" w:themeFillShade="BF" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeFillTint (Shading Background Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeFillTint is supplied, then it is applied to the RGB value of the themeFill color

Attributes	Description
	(from the theme part) to determine the final color applied to this border. The themeFillTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255 = 153 = 99(hex)$$ The resulting themeFillTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6) = 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting shading's fill attribute: `<w:top w:val="single" w:sz="4" w:space="24" w:fill="95B3D7" w:themeFillColor="accent2" w:themeFillTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).

Attributes	Description
themeShade (Shading Pattern Theme Color Shade)	Specifies the shade value applied to the supplied theme color (if any) for this shading color. If the themeShade is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border. The themeShade value is stored as a hex encoding of the shade value (from 0 to 255) applied to the current border. [*Example*: Consider a shade of 40% applied to a background shading color in a document. This shade is calculated as follows: $$S_{xml} = 0.4 * 255$$ $$= 102$$ $$= 66(hex)$$ Te resulting themeShade value in the file format would be 66. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Shade}_{\mathrm{percentage}}$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is C0504D. The equivalent HSL color value would be $\left(\frac{1}{360}, 0.48, 0.53\right)$. Applying the shade formula with a shade percentage of 75% to the luminance, we get: $$L' = 0.53 * 0.75$$ $$= 0.39698$$ Taking the resulting HSL color value of $\left(\frac{1}{360}, 0.48, 0.39698\right)$and converting back to RGB, we get 943634. This transformed value can be seen in the resulting background's color attribute: `<w:shd w:color="943634" w:themeColor="accent2" w:themeShade="BF" />` *end example*]

Attributes	Description
	The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
themeTint (Shading Pattern Theme Color Tint)	Specifies the tint value applied to the supplied theme color (if any) for this shading instance. If the themeTint is supplied, then it is applied to the RGB value of the themeColor color (from the theme part) to determine the final color applied to this border. The themeTint value is stored as a hex encoding of the tint value (from 0 to 255) applied to the current border. [*Example*: Consider a tint of 60% applied to a border in a document. This tint is calculated as follows: $$T_{xml} = 0.6 * 255$$ $$= 153$$ $$= 99(hex)$$ The resulting themeTint value in the file format would be 99. *end example*] Given an RGB color defined as three hex values in RRGGBB format, the shade is applied as follows: • Convert the color to the HSL color format (values from 0 to 1) • Modify the luminance factor as follows: $$\mathrm{L}' = \mathrm{L} * \mathrm{Tint}_{\mathrm{pct}} + \left(1 - \mathrm{Tint}_{\mathrm{pct}}\right)$$ • Convert the resultant HSL color to RGB [*Example*: Consider a document with a background using the accent2 theme color, whose RGB value (in RRGGBB hex format) is 4F81BD. The equivalent HSL color value would be $\left(\frac{213}{360}, 0.45, 0.53\right)$. Applying the tint formula with a tint percentage of 60% to the luminance, we get: $$L' = 0.53 * 0.6 + (1 - .6)$$ $$= 0.71$$ Taking the resulting HSL color value of $\left(\frac{213}{360}, 0.45, 0.71\right)$and converting back to RGB, we get 95B3D7. This transformed value can be seen in the resulting shading's color attribute: `<w:shd w:color="95B3D7" w:themeColor="accent2"`

Attributes	Description
	`w:themeTint="99" />` *end example*] The possible values for this attribute are defined by the ST_UcharHexNumber simple type (§2.18.106).
val (Shading Pattern)	Specifies the pattern which shall be used to lay the pattern color over the background color for this paragraph shading. This pattern consists of a mask which is applied over the background shading color to get the locations where the pattern color should be shown. Each of these possible masks are shown in the simple type values referenced below. [*Example*: Consider a shaded paragraph which uses a 10 percent foreground fill, resulting in the following WordprocessingML: `<w:shd w:val="pct10" .../>` This shading val is `pct10`, indicating that the border style is a 10 percent foreground fill mask. *end example*] The possible values for this attribute are defined by the ST_Shd simple type (§2.18.85).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_Shd">
   <attribute name="val" type="ST_Shd" use="required"/>
   <attribute name="color" type="ST_HexColor" use="optional"/>
   <attribute name="themeColor" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeShade" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="fill" type="ST_HexColor" use="optional"/>
   <attribute name="themeFill" type="ST_ThemeColor" use="optional"/>
   <attribute name="themeFillTint" type="ST_UcharHexNumber" use="optional"/>
   <attribute name="themeFillShade" type="ST_UcharHexNumber" use="optional"/>
</complexType>
```

2.4.36 tbl (Table)

This element specifies the contents of a table present in the document. A *table* is a set of paragraphs (and other block-level content) arranged in *rows* and *columns*. Tables in WordprocessingML are defined via the tbl element, which is analogous to the HTML `table` tag.

[*Example*: Consider an empty one-cell table (i.e.; a table with one row, one column) and 1 point borders on all sides:

This table is represented by the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblW w:w="5000" w:type="pct"/>
    <w:tblBorders>
      <w:top w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:left w:val="single" w:sz="4 w:space="0" w:color="auto"/>
      <w:bottom w:val="single" w:sz="4" w:space="0" w:color="auto"/>
      <w:right w:val="single" w:sz="4" w:space="0" w:color="auto"/>
    </w:tblBorders>
  </w:tblPr>
  <w:tblGrid>
    <w:gridCol w:w="10296"/>
  </w:tblGrid>
  <w:tr>
    <w:tc>
      <w:tcPr>
        <w:tcW w:w="0" w:type="auto"/>
      </w:tcPr>
      <w:p/>
    </w:tc>
  </w:tr>
</w:tbl>
```

This table specifies table-wide properties of 100% of page width using the tblW element (§2.4.61); a the set of table borders using the tblBorders element (§2.4.38); the table grid which defines a set of shared vertical edges within the table using the tblGrid element (§2.4.44); and a single table row using the tr element (§2.4.75). *end example*]

```
<complexType name="CT_Tbl">
    <sequence>
        <group ref="EG_RangeMarkupElements" minOccurs="0" maxOccurs="unbounded"/>
        <element name="tblPr" type="CT_TblPr"/>
        <element name="tblGrid" type="CT_TblGrid"/>
        <group ref="EG_ContentRowContent" minOccurs="0" maxOccurs="unbounded"/>
    </sequence>
</complexType>
```

2.4.37 tblBorders (Table Borders Exceptions)

This element specifies the set of borders for the edges of the parent table row via a set of table-level property exceptions, using the six border types defined by its child elements.

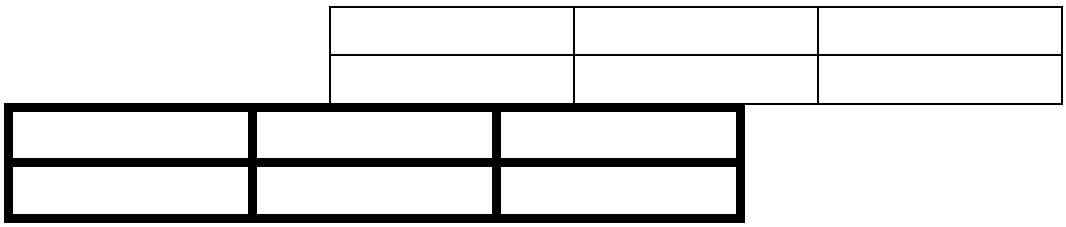
If the cell spacing for any row is non-zero as specified using the tblCellSpacing element (§2.4.41; §2.4.42; §2.4.43), then there is no border conflict and the table-level exception border shall be displayed.

If the cell spacing is zero, then there is a conflict [*Example*: Between the left border of all cells in the first column and the left border of the table-level exceptions. *end example*], which shall be resolved as follows:

- If there is a cell border, then the cell border shall be displayed
- If there is no cell border, then the table-level exception border shall be displayed

If this element is omitted, then this table shall have the borders specified by the associated table level borders (§2.4.38).

[*Example*: Consider a table in which the final two rows have a set of table-level property exceptions giving them a thicker set of table borders, as follows:



These table borders are specified via a set of table-level property exceptions using the following WordprocessingML:

```
<w:tr>
  <w:tblPrEx>
    <w:tblBorders>
      <w:top w:val="single" w:sz="24" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:left w:val="single" w:sz="24" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:bottom w:val="single" w:sz="24" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:right w:val="single" w:sz="24" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:insideH w:val="single" w:sz="24" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:insideV w:val="single" w:sz="24" w:space="0" w:color="000000"
w:themeColor="text1"/>
    </w:tblBorders>
  </w:tblPrEx>
</w:tr>
```

The tblBorders element specifies the set of table borders applied to the final two rows in this table as part of the table-level property exceptions. *end example*]

Parent Elements
tblPrEx (§2.4.57); tblPrEx (§2.4.58)

Child Elements	Subclause
bottom (Table Bottom Border)	§2.4.4
insideH (Table Inside Horizontal Edges Border)	§2.4.17
insideV (Table Inside Vertical Edges Border)	§2.4.20
left (Table Left Border)	§2.4.27
right (Table Right Border)	§2.4.32
top (Table Top Border)	§2.4.71

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblBorders">
   <sequence>
      <element name="top" type="CT_Border" minOccurs="0"/>
      <element name="left" type="CT_Border" minOccurs="0"/>
      <element name="bottom" type="CT_Border" minOccurs="0"/>
      <element name="right" type="CT_Border" minOccurs="0"/>
      <element name="insideH" type="CT_Border" minOccurs="0"/>
      <element name="insideV" type="CT_Border" minOccurs="0"/>
   </sequence>
</complexType>
```

2.4.38 tblBorders (Table Borders)

This element specifies the set of borders for the edges of the current table, using the six border types defined by its child elements.

If the cell spacing for any row is non-zero as specified using the tblCellSpacing element (§2.4.41; §2.4.42; §2.4.43), then there is no border conflict and the table border (or table-level exception border, if one is specified) shall be displayed.

If the cell spacing is zero, then there is a conflict [*Example*: Between the left border of all cells in the first column and the left border of the table. *end example*], which shall be resolved as follows:

- If there is a cell border, then the cell border shall be displayed
- If there is no cell border but there is a table-level exception border on this table row, then the table-level exception border shall be displayed
- If there is no cell or table-level exception border, then the table border shall be displayed

If this element is omitted, then this table shall have the borders specified by the associated table style. If no borders are specified in the style hierarchy, then this table shall not have any table borders.

[*Example*: Consider a table with no associated table style, which defines a set of table borders via direct formatting as follows:

These table borders are specified using the following WordprocessingML:

```
<w:tbl>
  <w:tblPr>
    <w:tblW w:w="0" w:type="auto"/>
    <w:tblBorders>
      <w:top w:val="single" w:sz="4" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:left w:val="single" w:sz="4" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:bottom w:val="single" w:sz="4" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:right w:val="single" w:sz="4" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:insideH w:val="single" w:sz="4" w:space="0" w:color="000000"
w:themeColor="text1"/>
      <w:insideV w:val="single" w:sz="4" w:space="0" w:color="000000"
w:themeColor="text1"/>
    </w:tblBorders>
    …
  </w:tblPr>
  …
</w:tbl>
```

The tblBorders element specifies the set of table borders applied to the current table. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Child Elements	Subclause

Child Elements	Subclause
bottom (Table Bottom Border)	§2.4.4
insideH (Table Inside Horizontal Edges Border)	§2.4.17
insideV (Table Inside Vertical Edges Border)	§2.4.20
left (Table Left Border)	§2.4.27
right (Table Right Border)	§2.4.32
top (Table Top Border)	§2.4.71

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblBorders">
   <sequence>
      <element name="top" type="CT_Border" minOccurs="0"/>
      <element name="left" type="CT_Border" minOccurs="0"/>
      <element name="bottom" type="CT_Border" minOccurs="0"/>
      <element name="right" type="CT_Border" minOccurs="0"/>
      <element name="insideH" type="CT_Border" minOccurs="0"/>
      <element name="insideV" type="CT_Border" minOccurs="0"/>
   </sequence>
</complexType>
```

2.4.39 tblCellMar (Table Cell Margin Defaults)

This element specifies the default cell margin settings for all cells in the current table. These setting may be overridden by the table cell margin definition specified by the tcMar element contained within the table cell's properties (§2.4.65) or by a set of table-level property exceptions (§2.4.40).

If this element is omitted, then it shall inherit the table cell margins from the associated table style. If table margins are never specified in the style hierarchy, then each margin shall use its default margin size (see child element definitions).

[*Example*: Consider a table defined to have default cells margins of 0.1 inches for all sides, as follows:

R1C1	R1C2
R2C1	R2C2

This set of default table cell margins would be specified using the following WordprocessingML:

```
<w:tblPr>
  <w:tblCellMar>
    <w:top w:w="144" w:type="dxa"/>
    <w:left w:w="144" w:type="dxa"/>
    <w:bottom w:w="144" w:type="dxa"/>
    <w:right w:w="144" w:type="dxa"/>
  </w:tblCellMar>
  …
</w:tblPr>
```

The tblCellMar element as a child of tblPr specifies the set of default cell margins for all cells in the current table, in this case, 144 twentieths of a point. *end example*]

Parent Elements
tblPr (§2.7.5.3); tblPr (§2.7.5.4); tblPr (§2.4.55); tblPr (§2.4.56)

Child Elements	Subclause
bottom (Table Cell Bottom Margin Default)	§2.4.5
left (Table Cell Left Margin Default)	§2.4.26
right (Table Cell Right Margin Default)	§2.4.29
top (Table Cell Top Margin Default)	§2.4.72

The following XML Schema fragment defines the contents of this element:

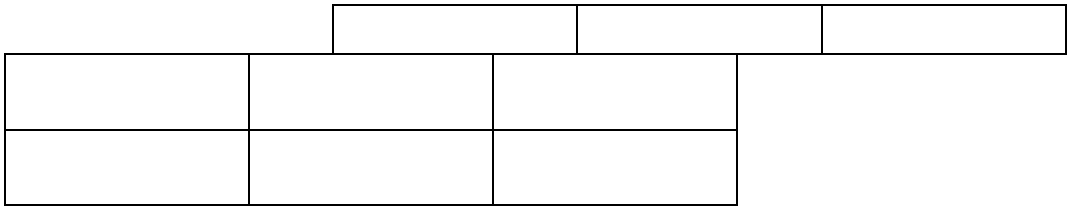
```
<complexType name="CT_TblCellMar">
   <sequence>
      <element name="top" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="left" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="bottom" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="right" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.4.40 tblCellMar (Table Cell Margin Exceptions)

This element specifies a set of cell margins for all cells in the parent table row via a set of table-level property exceptions. These settings may be overridden by the table cell margin definition specified by the tcMar element contained within the table cell's properties (§2.4.40).

If this element is omitted, then it shall inherit the table cell margins from the table-level cell margins (§2.4.39).

[*Example*: Consider a table whose final two rows are defined to have default cell margins of 0.1 inches for all sides via a table-level property exception, as follows:



This set of table cell margin exceptions is specified using the following WordprocessingML:

```
<w:tblPrEx>
  <w:tblCellMar>
    <w:top w:w="144" w:type="dxa"/>
    <w:left w:w="144" w:type="dxa"/>
    <w:bottom w:w="144" w:type="dxa"/>
    <w:right w:w="144" w:type="dxa"/>
  </w:tblCellMar>
  …
</w:tblPrEx>
```

The tblCellMar element as a child of tblPrEx specifies the set of default cell margins for all cells in final two rows in current table, in this case, 144 twentieths of a point on all sides. *end example*]

Parent Elements
tblPrEx (§2.4.57); tblPrEx (§2.4.58)

Child Elements	Subclause
bottom (Table Cell Bottom Margin Default)	§2.4.5
left (Table Cell Left Margin Default)	§2.4.26
right (Table Cell Right Margin Default)	§2.4.29
top (Table Cell Top Margin Default)	§2.4.72

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblCellMar">
   <sequence>
      <element name="top" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="left" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="bottom" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
      <element name="right" type="CT_TblWidth" minOccurs="0" maxOccurs="1"/>
   </sequence>
</complexType>
```

2.4.41 tblCellSpacing (Table Cell Spacing Exception)

This element specifies a table cell spacing exception for all cells in the parent table row as part of a set of table-level property exceptions. If specified, this element specifies the minimum amount of space which shall be left between all cells in the parent row after including the width of the table borders in the calculation. This setting shall be superseded by the row cell spacing value (§2.4.42). It is important to note that table-level cell spacing shall be added outside of the text margins, which shall be aligned with the innermost starting edge of the text extents in a table cell.

This value is specified in the units applied via its type attribute. Any width value of type `pct` or `auto` for this element shall be ignored.

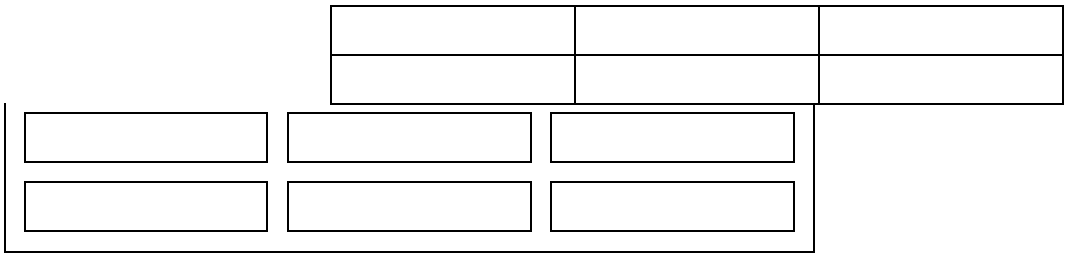
[*Example*: Consider a table whose first cell has a six point wide table border, and a table cell spacing value of 0.01 inches. The resulting table would have 0.01 inches of space between each table cell regardless of the width of the cell border, as follows (notice that no border is covered by any other border):

R1C1	R1C2
R2C1	R2C2

end example]

If this element is omitted, then the row shall inherit the table cell spacing from the table-level cell spacing setting (§2.4.39), excepting the case of a row level override.

[*Example*: Consider a table whose final two rows are defined to have cell spacing of 0.1 inches for all sides via a table-level property exception, as follows:



This table cell spacing exception is specified using the following WordprocessingML:

```
<w:tblPrEx>
  <w:tblCellSpacing w:w="144" w:type="dxa">
  …
</w:tblPrEx>
```

The tblCellSpacing element as a child of tblPrEx specifies the default cell spacing between all cells in final two rows in the current table, in this case 144 twentieths of a point. *end example*]

Parent Elements
tblPrEx (§2.4.57); tblPrEx (§2.4.58)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
w (Table Width Value)	Specifies the value of the width property being defined by the parent element. This property is used to define various properties of a table, including: cell spacing, preferred widths, and table margins. If this attribute is omitted, then its value shall be assumed to be 0. [*Example*: Consider a table with a bottom margin with a width of 302, as follows: `<w:bottom w:w="302" w:type="dxa" />` The value in the w attribute shall therefore be used to determine the width being specified in the context of the units specified in the type attribute. In this case, the type is twentieths of a point (dxa), so the width is 302 twentieths of a point (.2097 inches). *end example*] The possible values for this attribute are defined by the ST_DecimalNumber simple type (§2.18.16).

The following XML Schema fragment defines the contents of this element:

```
<complexType name="CT_TblWidth">
   <attribute name="w" type="ST_DecimalNumber"/>
   <attribute name="type" type="ST_TblWidth"/>
</complexType>
```

2.4.42 tblCellSpacing (Table Row Cell Spacing)

This element specifies the default table cell spacing (the spacing between adjacent cells and the edges of the table) for all cells in the parent row. If specified, this element specifies the minimum amount of space which shall be left between all cells in the table including the width of the table borders in the calculation. It is important to note that row-level cell spacing shall be added inside of the text margins, which shall be aligned with the innermost starting edge of the text extents in a cell without row-level indentation or cell spacing. Row-level cell spacing shall not increase the width of the overall table.

This value is specified in the units applied via its type attribute. Any width value of type `pct` or `auto` for this element shall be ignored.

[*Example*: Consider a table whose first cell has a six point wide table border, and a table cell spacing value of 0.01 inches. The resulting table would have 0.01 inches of space between each table cell regardless of the width of the cell border, as follows (notice that no border is covered by any other border):

R1C1	R1C2
R2C1	R2C2

end example]

If this element is omitted, then the cells in this row shall inherit the cell spacing from the associated table level properties.

[*Example*: Consider a table where the second row has a cell spacing of 0.1 inches for all sides specified via the table row properties as follows:

This table row cell spacing is specified using the following WordprocessingML:

```
<w:trPr>
  <w:tblCellSpacing w:w="144" w:type="dxa">
  …
</w:trPr>
```

The tblCellSpacing element as a child of trPr specifies the default cell spacing between all cells in the current row, in this case 144 twentieths of a point. *end example*]

Parent Elements
trPr (§2.7.5.10); trPr (§2.7.5.11); trPr (§2.4.78); trPr (§2.4.79)

Attributes	Description
type (Table Width Type)	Specifies the units of the width property being defined by the parent element's w attribute. This property is used to define various properties of a table, including: cell spacing, preferred width, and table margins. If this attribute is omitted, then its value shall be assumed to be dxa (twentieths of a point). [*Example*: Consider a table with a table cell bottom cell spacing with a type of dxa, as follows: `<w:bottom ... w:type="dxa" />` This type shall therefore be used to interpret the width specified in the w attribute as a value in twentieths of a point. *end example*] The possible values for this attribute are defined by the ST_TblWidth simple type (§2.18.97).
