NATIONAL BUREAU OF ECONOMIC RESEARCH
1050 Massachusetts Avenue
Cambridge, MA 02138
April 2018, Revised July 2019

We study immigrant entrepreneurship in 2007 and 2012 using the Survey of Business Owners. First-generation immigrants create about 25% of new firms in America, but this share exceeds 40% in some states. Immigrant-owned firms tend to create fewer jobs than native-owned firms, have comparable pay levels, offer fewer benefits, and engage more in international activities. Immigrant-founded firms in high-tech sectors more closely resemble native-founded firms than in low-tech sectors. Prominent tech clusters display quite pronounced shares of immigrant entrepreneurs, with stronger high-tech immigrant entrepreneurs being especially present. Second-generation immigrants tend to show intermediate firm traits indicative of business assimilation. The views expressed herein are those of the authors and do not necessarily reflect the views of the National Bureau of Economic Research.

NBER working papers are circulated for discussion and comment purposes. They have not been peer-reviewed or been subject to the review by the NBER Board of Directors that accompanies official NBER publications.

ABSTRACT

We study immigrant entrepreneurship and firm ownership in 2007 and 2012 using the Survey of Business Owners (SBO). The survival and growth of immigrant-owned businesses over time relative to native-founded companies is evaluated by linking the 2007 SBO to the Longitudinal Business Database (LBD). We quantify the dependency of the United States as a whole, as well as individual states, on the contributions of immigrant entrepreneurs in terms of firm formation and job creation. We describe differences in the types of businesses started by immigrants and the quality of jobs created by their firms. First-generation immigrants create about 25% of new firms in the United States, but this share exceeds 40% in some states. In addition, Asian and Hispanic second-generation immigrants start about 6% of new firms. Immigrant-owned firms, on average, create fewer jobs than native-owned firms, but much of this is explained by the industry and geographic location of the firms. Immigrant-owned firms pay comparable wages, conditional on firm traits, to native-owned firms, but are less likely to offer benefits.

1 Introduction

Immigrant entrepreneurship plays an important role in the American economy. Immigrants start about 25% of all U.S. firms in the Survey of Business Owners data during 2008-2012, and this share rises to above 40% in states like California and New York. These immigrant-founded firms provide jobs and innovations, impacting the lives of natives. Immigrant entrepreneurs frequently show up in popular press business narratives, legislation and lobbying discussions, and the founding histories of many prominent firms. Among Fortune 500 companies, about 40% were founded by first- or second-generation immigrants (Partnership for a New American Economy 2011).

The prominence of immigrant entrepreneurs, aided by expanding economic data sets for research, has yielded a burgeoning academic literature. Many early studies establish that immigrants are more likely to enter self-employment and other forms of entrepreneurship than natives.¹ A few recent studies also identify some important properties of these firms, such as Wang and Liu (2005) showing that U.S. firms with immigrant owners are more likely to export goods and services and have operations abroad. Brown et al. (2018) document a greater patenting/innovation rate for immigrant-founded firms.² Yet, this comparison between immigrant- and native-founded firms remains incomplete, and relatively little is known about the broader impacts of immigrant entrepreneurs in terms of job creation and economic growth.³ Given that over a quarter a new firm births are connected to immigrant entrepreneurs—a share that is continually rising—an accurate characterization of these inputs is important for enhanced business and economic analysis.

Such a depiction would be incomplete without a consideration of the vast heterogeneity in immigrant entrepreneurship, which parallels in many ways the diversity of entrepreneurship more broadly. Immigrant entrepreneurs range from small “mom and pop” stores in low-tech

¹Examples include Borjas (1986), Lofstrom (2002), Clark and Drinkwater (2000, 2006), Fairlie and Meyer (2003), Schuetze and Antecol (2007), Fairlie et al. (2010), Lofstrom et al. (2014), Kerr and Kerr (2017), and Brown et al. (2018). Examples of studies for high-tech immigrant entrepreneurship include Saxenian (1999, 2002), Anderson and Platzer (2006), Monti et al. (2007), Wadhwa et al. (2007), and Hart and Acs (2011).

²Brown et al. (2018) consider the 2007 SBO and 2014 Annual Survey of Entrepreneurs. Their important study finds that immigrant entrepreneurs have distinct motivations for starting a business as compared to natives, and immigrant entrepreneurs are more likely to engage in R&D and innovation. This is especially true among college-educated founders.

³Immigrant scientists and engineers have received closer study. For example, Hunt and Gauthier-Loiselle (2010), Kerr and Lincoln (2010), Hunt (2011), Kerr et al. (2015a,b), Peri et al. (2015), and Breschi et al. (2017). Kerr (2017) provides a review.

settings to high-tech start-ups in top clusters like Silicon Valley. These firms are likely to look quite different from each other, and they may also be more or less similar to their closest native peers. We need a better understanding of the range of industries influenced by immigrant entrepreneurs and their impact on U.S. economic regions as diverse as Montana and Florida.

This study quantifies many of these features using a novel data platform—the Survey of Business Owners (SBO) for 2007 and 2012, combined with the Longitudinal Business Database (LBD) for 2007-2011. The SBO allows us to measure the number and quality of jobs created by immigrant entrepreneurs, and we can separate out firms in high-tech vs. low-tech industries. The SBO information spans company payroll per employee, usage of full-time vs. temporary workers, and the provision of various employee benefits such as health insurance and paid time off. We also examine differences between native- and immigrant-founded firms in terms of their international activities and start-up and expansion financing.

To preview some of our results, dependency on immigrant founders varies substantially across regions in America, from less than 5% in Idaho and North Dakota to more than 40% in “gateway” states like California. Immigrant-founded firms tend to have fewer employees than native-founded firms, but they have higher labor productivity (receipts per employee), are more likely to survive to 2011, and grow employment at a slightly faster pace. The jobs created by immigrant-founded firms provide comparable wages, but these firms offer significantly fewer benefits like healthcare or 401k plans. Reflecting the early literature, immigrant-founded firms engage in more extensive international activities. Regression analyses show that these differences are partly explained by industries in which immigrant-founded startups operate, but a gap persists even with a very stringent set of control variables. High-tech firms founded by immigrants tend to look more like their native peers than those in low-tech industries, but usually the results are of similar qualitative direction regardless of sector. There are also differences by owner ethnicity, but relatively fewer differences by owner education level.

The depth of the survey also allows us to consider entrepreneurship inside vs. outside of prominent tech clusters. We find that immigrant-founded companies account for more than 40% of high-tech startups in leading clusters. As their traits tend to resemble those of native-founded companies in these clusters, most of the impact appears to come through sheer quantity of immigrant entrepreneurs agglomerating in key hubs. Finally, we compare the activity of first- generation immigrants to that of second-generation immigrants to measure

whether the firms founded by U.S.-born entrepreneurs with foreign-born parents more closely resemble the companies started by native entrepreneurs.

The new firms that we study have an important impact, as young firms account for almost all of the net job growth in America (Haltiwanger et al. 2013). First-generation immigrants found or co-founded 23.7% and 26.0% of these new firms in 2007 and 2012, respectively. As entering employment sizes in recent cohorts are mostly similar for immigrants and natives, immigrant entrepreneurs have accounted for a similar share of new jobs in young companies in both surveys. Applying these shares to overall U.S. private-sector employment in new firms as captured by the Business Dynamics Survey would estimate job provision by young immigrant-owned firms of 3-4 million workers. Further incorporating second-generation immigrants would raise the estimates to 4-5 million workers. While these calculations are only approximate, they give a sense to the ongoing contribution to the U.S. economy of immigrant entrepreneurship.

These results inform the potential economic impact of policy reforms. In 2019, the United States has the EB-5 visa that targets wealthy immigrants capable of investing a million dollars into a U.S.-based business, but the country lacks a program that facilitates other aspiring migrant entrepreneurs (or graduating students from U.S. schools who wish to create a firm vs. entering paid employment).⁴ Consequently, the vast majority of immigrant entrepreneurs enter the United States through the broad migration routes of family-based visas or employment-sponsored visas (with entrepreneurship becoming possible once a green card is obtained). With this diffuse and indirect origin, the outcomes of immigrant entrepreneurship must be observed in the economy vs. inferred from rules or policy requirements.⁵

The rest of this study is organized as follows. Section 2 reviews the literature on immigrant entrepreneurship and presents theories as to why immigrants choose to enter entrepreneurship. Section 3 describes the SBO data platform and provides descriptive tabulation. Section 4 uses

⁴By comparison, Canada, France and the U.K. have distinct visas for foreign entrepreneurs with various incentives aimed at attracting more start-ups. The French Tech Ticket program was initiated in 2016, Canada's start-up visa scheme in 2013, and the UK's Entrepreneur Visa in 2008. Other examples include Chile, Cyprus, Denmark, Finland, Ireland, Lithuania, the Netherlands, New Zealand, Singapore, Spain, and Taiwan. President Obama sought to increase access to entrepreneur visas through actions like the International Entrepreneur Rule, but the Trump administration has paused these efforts indefinitely. Kerr (2019) describes efforts to attract global talent in America and other countries. Many U.S. cities seek to attract immigrant entrepreneurs and their economic stimulus, such as the Competition THRIVE program in New York City, the Office of New Americans in Chicago, the International Institute of St. Louis, and the Welcoming Cities initiatives in places such as Pittsburgh.

⁵The time in America before starting the venture could boost the chances of success. Mata and Alves (2018) show that immigrant firms have lower rate of survival but experience in host countries improves the chances of survival.

regression analyses to formally compare immigrant- and native-owned businesses. Section 5 provides two extensions: isolating top metropolitan areas and comparing first- versus second-generation immigrants. The final section concludes with some discussion of future research opportunities.

2 Theoretical and Conceptual Background

A growing body of work documents the higher rate at which immigrants enter entrepreneurship in America than natives (Fairlie 2012). This section explores some of the key findings from this literature and how theoretically we anticipate immigrant entrepreneurship in high-tech vs. low-tech industries to be different. As a first step, two candidate explanations for high rates of immigrant entrepreneurship can be dismissed. Most important, the phenomenon is broad-based in America and not simply due to immigrants from one source country or region being particularly entrepreneurial. Fairlie and Lofstrom (2013) use the 2007-2011 Current Population Survey (CPS) and confirm, among other things, that immigrant entrepreneurship is pervasive across ethnic groups. Consequently, as immigration to America is very diverse across education levels, industries, and regions, we anticipate substantial heterogeneity in the entrepreneurial population.

Second, immigrant entrepreneurship is not just an American phenomenon. The higher propensity of immigrants towards creating new firms is observed in other immigrant-receiving countries (OECD 2010). Unfortunately, the data on immigrant entrepreneurship globally are sparse and far from systematic or comparable over nations. However, the existing data are consistent in observing a higher rate of entrepreneurship among immigrants. The Centre for Entrepreneurs (2014) shows that over 17% of U.K. immigrants start a firm, compared to 10% of natives. For Canada, 19.6% of immigrants become self-employed (5.3% own a firm), whereas the comparable numbers are 16.1% and 4.8% for natives (Green et al. 2016). For Australia, the overall rate of self-employment is about 12%, with immigrants more likely to enter self-employment than natives (Atalay et al. 2014).⁶

⁶The Centre for Entrepreneurs (2014) calculates that immigrants start 14% of all U.K. firms, with particular concentration around London. Comparable statistics for Canada and Australia are not possible, but Momani (2016) reports that 24% of small- and medium-sized enterprise owners in Canada are immigrants.

2.1 Root Factors for Immigrant Entrepreneurship

While our study focuses on the United States, these common global patterns to immigrant entrepreneurship suggest that the root factors likely overlap across countries. We draw from the literature the four factors outlined next, which contribute directly and interact with each other. Some of these root factors act as a positive and pulling force for immigrant entrepreneurship, emphasizing the personality traits of immigrants, group-level benefits from joint selection into entrepreneurship, and so on. Other factors are darker and point to a push of immigrants into self employment due to weak opportunities for regular employment, discrimination, and similar challenges.

Entrepreneurial Personality: A substantial literature, reviewed by Åstebro et al. (2014) and Kerr, Kerr and Xu (2018), explores the degree to which entrepreneurs have a prototypical personality. On many dimensions of personality, such as the classic Big-5 personality traits, the literature finds very limited difference between entrepreneurs and wage workers. The bigger differences instead emerge around factors such as the willingness or ability to tolerate risk and uncertainty, self-efficacy (the belief in one’s ability to complete tasks and fill roles), internal locus of control (the belief that one’s decisions control the outcomes of life vs. external factors), and the need for achievement. The required tolerance for risk has been closely studied (e.g., Kihlstrom and Laffont 1979, Hvide and Panos 2014) and Kerr, Kerr, and Dalton (2019) find survey and experimental evidence consistent with these personality factors.

There may be a conceptual connection of these personality traits to immigration. Leaving one’s home and moving abroad frequently involves uncertainty and risk, and migrants must often believe in themselves and their power to create a life in their new home. The choice to migrate may select on individuals with these traits, and the duration within the new home may further engender them. For example, a young migrant who successfully gets started in America may endogenously acquire a greater tolerance for risk and belief in her capabilities to produce the outcomes she desires. While the empirical verification of these linkages remains incomplete, the act of migration may capture a pool of individuals with personalities more aligned to opening up a business.

Conditional on being an entrepreneur (which will be true throughout our empirical work), we conjecture that these personality forces will have relatively limited differences between high-tech and low-tech industries. One can easily imagine the poorest of migrants being the most

selected on these dimensions and overcoming the most adversities (per the classic American dream). Broader population rates of entrepreneurship by immigrant group could be affected but are beyond this study’s data scope.

Opportunity-Based Migration: A feature related to the selection to migrate is the opportunity-based nature of much of immigration. While some migration is sadly forced (e.g., refugees), much of immigration occurs when individuals seek opportunities (and much of the missing benefits of migration happen when these intentions are blocked, such as Clemens 2011). This occurs within regions (e.g., low-skilled migration from India to work in Gulf States) and on global scales (e.g., flocking of bankers to leading financial centers). The United States has long been a favored destination for prospective entrepreneurs due to its open and mostly competitive markets, its complementary service providers (such as financing), and its content-sized product markets and customer bases. For many entrepreneurial immigrants, it is the dream destination.

While we believe this factor promotes immigrant entrepreneurship across the board, the impact for high-tech sectors is likely to be more pronounced. America provides prospective high-tech entrepreneurs access to the scientific frontier, the world’s most vibrant talent clusters, deep venture capital markets, and so forth. Akcigit, Baslandze, and Stantcheva (2016) demonstrate that the most productive immigrant inventors are the most sensitive to higher tax rates, and Kerr (2010) documents how immigrants are particularly fast to migrate to locations experiencing breakthrough inventions. These patterns suggest that high-tech entrepreneurs have the most to gain from migration to America vs. other potential destinations.⁷

Weaker Labor Market Prospects: Entrepreneurship does not happen at equal rates across the education and skill distribution. First, at a macro level, entrepreneurship exhibits a U-shaped pattern with respect to the full distribution of skills, disproportionately occurring at the upper and lower tails of the distribution (Poschke 2013; Levine and Rubinstein 2017). Åstebro, Chen and Thompson (2011) colorfully describe these tails as “stars” and “misfits.” Second, Hegde and Tumlinson (2018) provide provocative evidence that within each education rank (grade by grade), individuals are more likely to start their own business if they have high skill levels and abilities compared to others with the same credentials.

⁷This potential for opportunity-based migration is strong enough to affect early education choices made in sending countries (e.g., Chand and Clemens 2008; Gibson and McKenzie 2011). Akee et al. (2013) show that migrants with a history of entrepreneurship in their home country are more likely to be entrepreneurs in their new nation.

Both of these patterns connect into immigrant entrepreneurship. At the macro level, immigrants are more prevalent at the lower and higher ends of the education distribution than natives in America. Among those aged 18 and older, immigrants are 20% more likely than natives to have ended their education with a high school diploma or less, but they are also 40% more likely than natives to have earned a doctorate or equivalent degree (American Community Survey 2012). Immigration at the lower end of the education distribution is connected to both employment-based migration for low-skilled work (e.g., agricultural visas) and family-based migration; these groups arrive disproportionately from Central and Latin America and connect in part to unauthorized inflows. Immigration at the upper end of the education ladder connects more to student and skilled worker visas.

At a more micro level, immigrants can be pushed towards entrepreneurship due to a lack of labor market opportunities commensurate with their skill set. Many immigrants experience downward mobility and underemployment when they first arrive in a destination country. This is often due to an under-recognition of education and experience gained in their home country (e.g., Friedberg 2000; Li 2001; Batalova, Fix and Creticos 2008), as it is more difficult for employers to assess foreign school quality or validate credentials compared to a domestic candidate. For some migrants, this temporary setback is rectified by gaining additional experience and/or education after migration (e.g., Creese and Weibe 2012), but others look to entrepreneurship as an attractive alternative.

Given the pervasive nature of this factor, it is not theoretically clear if it should impact high-tech or low-tech industries more. The challenges presented by discrimination (e.g., Oreopoulos 2011; Edo, Jacquemet, and Yannelis 2013) or a lack of employment authorization may be more acute in low-tech work. The founding entrepreneur may also decide to start a business because of comparative access to underemployed or undocumented individuals, potentially gaining lower labor costs compared to competitors.

For high-tech industries, it is likely that the pathways to wage work are stronger for immigrants and more consistent, due to the greater transportability of technical skills and the deeper pool of the labor markets. According to 2012 ACS statistics, immigrants are twice as likely as natives to be employed in a STEM occupation, and thus employers will have greater incentives to recruit effectively in these markets. On the other hand, small proportionate differences in wage versus entrepreneurial outcomes become much larger as one gets to the highest

end of the skill distribution.

Co-Ethnic Social Bond: Connected to the above factors, immigrant entrepreneurs display a remarkable concentration—varying by ethnic group—in terms of the sectors in which they operate. Prominent low-tech examples include Vietnamese nail care salons, Korean dry cleaners, Gujarti Indian motels, and Punjabi Indian convenience stores. In the pre-Uber days, immigrant groups often drove most of the taxis in a city, with the particular ethnic group varying by city. Studies of this entrepreneurial concentration highlight the benefits obtained by group specialization and shared knowledge when strong social networks undergird the ethnic community, and this concentration becomes a natural pathway to employment and potential entrepreneurship for new arrivals.⁸

There is similar evidence in advanced high-tech sectors of this specialization and co-ethnic connection, albeit likely less pronounced. Hegde and Tumlinson (2014) document that venture investors are more likely to invest in a firm run by someone of the same ethnic background, and Gompers, Mukharlyamov, and Xuan (2016) document how venture inventors also co-invest with each other along ethnic lines. These co-ethnic connections are not necessarily efficient choices, as investors may be less careful for example, but speak again to the group-based concentration.

Consistent with this concentration, we later document in the SBO data that roughly half of immigrant-owned startups are in three sectors: accommodation and food services, retail trade, and professional and technical services. Native-owned firms are less concentrated. These group based factors appear strongest among low-tech services and trade segments, compared to the high-tech sector, due to the greater integration of high-tech firms in local markets.

2.2 Combining Features and Defining Business Traits

Our discussion highlights how all four of these root factors contribute to immigrant entrepreneurship, but likely to varying degrees for high-tech vs. low-tech industries. We conjecture that immigrant founders of high-tech firms are more likely to select into entrepreneurship due to positive pull factors, especially opportunity-based migration. Push factors like discrimination or weak labor market prospects are likely to be less important, although early stories of Silicon Valley immigrant entrepreneurs do mention perceptions of glass ceilings on advancement at

⁸For example, Kalnins and Chung (2006), Roth et al. (2012), Patel and Vella (2013), Andersson et al. (2014), Kerr and Mandorff (2015), and Battisti et al. (2016).

local tech incumbents.

Consequently, it is likely that high-tech immigrant entrepreneurs will be stronger and building better firms overall than their fellow migrants in low-tech settings. Some early confirmation of this selection effect is evident in the 2012 SBO data, where immigrant high-tech founders draw disproportionately from the highest education groups. Hunt (2011) also observes that the highest earning, most innovative, and most entrepreneurial immigrants arrived in the United States through temporary work or education visas, both which require a high level of education. These high-skilled individuals are quite mobile and often select locations where they will have the most opportunities. Indeed, we further conjecture that the strongest of high-tech immigrant entrepreneurs will be found in innovation clusters where firms compete in dynamic markets and diversity rates are high.⁹ In these competitive clusters, we further anticipate that the jobs created will need to match to a large degree what is being offered (wages and benefits) by comparable native-founded firms.

Immigrant founders in low-tech sectors are harder to predict. These founders are more likely to have migrated for non-work reasons and to have selected entrepreneurship as a way to build work opportunities for their families and/or communities. These firms will be similar to most small businesses in that few are seeking to disrupt a market or invent a new product or model (Hurst and Pugsley 2011). The 2012 SBO confirms that low-tech immigrant founders are disproportionately selected from low education groups. In this environment, we expect greater differences can emerge in terms of employment conditions and pay compared to comparable native-founded firms. This is especially true for family firms or firms who hire other immigrants, connected to lower worker productivity (e.g., learning the language), lack of competing employment offers, or similar.

Finally, the SBO data collect information on the global activities of firms. An extensive literature connects migration to trade.¹⁰ Global engagement could be focused on the exchange of ethnic goods and services, possibly linked to overseas diaspora communities, in ways that extend the product set of their host country. Migrants may also use their connections and global understanding to boost overseas sales of general products without ethnic specific components.

⁹For example, Saxenian (1996, 2000), Florida (2005), Fallick, Fleischman, and Rebitzer (2006), and Kerr (2019).

¹⁰Examples include Gould (1994), Head and Ries (1998), Rauch (2001), Rauch and Trindade (2002), Hatzi-georgiou and Lodefalk (2011), Bahar and Rapoport (2018), and Kerr (2018). Docquier and Rapoport (2012) provide a broader review.

We anticipate both low- and high-tech immigrant entrepreneurs to have a comparative advantage towards international engagement than their native peers. We further anticipate the benefits of this advantage to be greater with high-tech industries given the anecdotal and empirical accounts of global ethnic networks within high-tech industries (e.g., Saxenian 2002, Kerr 2008) and the typically greater market span for these products.

While our conceptual background has treated immigrant and native entrepreneurs as separate, there will be many firms with mixed founding teams. One starting hypothesis is that mixed teams would split the difference between pure immigrant and native founding teams, but one might also believe that the presence of one immigrant founder is enough to tilt characteristics (e.g., overseas linkages to promote engagement). It is also important to recognize that, by definition, mixed firms have more than one founder and so tend to be larger. Moreover, they may be less likely to occur in family-based settings or in smaller, rural locations. Thus, given this ambiguity, we will model them separately below in our empirical work. Moreover, we will consider some patterns for second-generation or later immigrant groups, where it is likely a partial assimilation has occurred (e.g., Masurel and Nijkamp 2004; Ibrahim and Galt 2011).

3 Data and Descriptive Tabulations

We use the restricted-access Survey of Business Owners (SBO) data housed in the Federal Statistical Research Data Centers (RDC). We employ the 2007 and 2012 SBOs and merge them with other Census Bureau data sources, including the Longitudinal Business Database (LBD). These data provide a rich and detailed platform to study immigrant entrepreneurship over across industries and geographies.¹¹

3.1 SBO 2007 and 2012 Data

The raw SBO files contain many types of firms, ranging from self-employed individuals who do not hire employees to small and large employer firms, some of which are publicly held. Our SBO analysis considers employer firms given our focus on understanding the quantity

¹¹Studies using the SBO micro data include those considering ethnic and minority entrepreneurs (e.g., Fairlie and Robb 2008, 2009; Fairlie 2012; Echeverri-Carroll and Kellison 2012; Gramlich and Perrin 2013; Mora and Davila 2014), job creation by owner gender (Conroy and Weiler 2016), and sources of start-up capital (e.g., Mencken and Tolbert 2016; Kerr et al. 2018). The Fiscal Policy Institute also published a 2012 report using the 2007 SBO regarding immigrant and native business owners.

and types of jobs created, rather than the self-employment patterns previously discussed in the literature.¹² We also exclude publicly owned firms from the sample, as it is impossible to accurately separate them into the immigrant- versus native-owned categories.

In 2007, our baseline sample of private employer firms includes 950 thousand companies. We exclude 1.4 million records for publicly owned firms and firms with no identifiable owner (e.g., estates, trusts, cooperatives, clubs, tribal entities) and 10.4 million records for self-employed incorporated non-employers. In 2012, our baseline sample of private employer firms includes 300 thousand companies. This 2012 sample comes after the exclusion of 224 thousand records for publicly owned companies and firms with no identifiable owner and 8.3 million records for self-employed individuals. The core sample is smaller in 2012 due to the introduction of two separate versions of the SBO survey instrument, one of which lacks detailed questions about the owners of the firm. This change does not impact our work as tabulation weights allow for population-based estimates.

We define new firms to be those entering in the five years prior to each survey. This segment captures the role of immigrants in recent entrepreneurial activity, and we use the term “startups” interchangeably. The number of new firm records that underlie the upcoming analyses is 139 thousand in 2007 and 48 thousand in 2012 (approximately 15% and 16% of the included SBO firms in 2007 and 2012, respectively). We track the new firms that enter prior to the 2007 SBO over time in the LBD, which provides annual employment and payroll information. This link affords measurement of the survival and growth patterns of these young firms during the critical early years of their operations.

The SBO records information on each owner of the firm, and we consider these owners to be the founders or entrepreneurs of the new firms that we study, although in a small share of cases the ownership of the firm will have changed hands by the time of the SBO survey. In some tabulations, we mirror the literature by classifying a firm as immigrant-owned if any of the firm’s owners is an immigrant. In our regression analyses, we typically parse into a separate category the firms with mixed immigrant and native ownership teams to allow for exclusively immigrant-owned companies to be compared to exclusively native-owned companies.

We define the high-tech industry based on the company NAICS code being in the list of high-tech industry NAICS codes in Hecker (2005) or Goldschlag and Miranda (2016) or being

¹²Immigrants account for about 15% of self-employed owners in SBO. We later provide complementary evidence using incorporated self-employed statistics from the American Community Survey.

an NAICS code listed as a patent-intensive industry in Doms et al. (2012).¹³ The SBO records data on around 97 thousand high-tech firms in 2007 and 48 thousand in 2012 (approximately 15% and 18% of the included SBO firms in 2007 and 2012, respectively). Among new firms, high-tech firms account for 16 thousand in 2007 and 8 thousand in 2012, or a 12% and 16% share respectively. Of course, a firm can be technologically sophisticated in a low-tech industry, and vice versa. Despite the imperfections of industry-based divisions, the ability to explore entrepreneurship in high-tech settings is a powerful addition to the literature.

We also investigate patterns for Metropolitan Statistical Areas (MSAs), following previous research on the high concentration of high-tech firms (e.g., Liu, Painter, and Wang 2014). High-tech MSAs are defined as the San Francisco Bay area, inclusive of Silicon Valley and San Jose, and the remaining top ten MSAs for housing high-tech firms using combined 2007 and 2012 SBOs: Atlanta, Boston, Chicago, Dallas, Houston, Los Angeles, Miami, New York, and Washington D.C.

Throughout this paper, Census Bureau disclosure requires observation counts be rounded, and all reported numbers are likewise rounded to four significant digits. We use the SBO tabulation weights in summary tables, and the noise-infused employment, payroll and receipt outcomes in 2007 (and for variables built upon those metrics).

3.2 SBO Descriptive Analysis

Tables 1a-c describe the SBO sample for new firms, with parallel tabulations for all firms being found in Appendix Tables A1a-c. In Table 1a, 26% of new firms formed in 2012 have an immigrant founder, which is comparable to prior work and other data approaches.¹⁴ Immigrant-owned firms have fewer employees but slightly higher receipts per employee.¹⁵ Receipts include the total revenue and business done by domestic establishments of the firm, excluding foreign operations; values are reported in thousands of nominal dollars. Immigrant-owned firms also

¹³High-tech industries include NAICS 333, 335, 1131-2, 2111, 2211, 3241, 3251-6, 3259, 3341-6, 3364, 3369, 3391, 3399, 4234, 4861-2, 4869, 5112, 5161, 5171-4, 5179, 5181-2, 5191, 5211, 5232, 5413, 5415-7, 5511, 5612, and 8112.

¹⁴Kerr and Kerr (2017) measure immigrant entrepreneurship through the Longitudinal Employer Household Dynamics (LEHD) database, a very large administrative dataset collected by the Census Bureau. Relative to the SBO, these data cover a much greater number of establishments, but the firm and founder details in the SBO are much richer. Kerr and Kerr (2017) find that the share of immigrant founders steadily increased between 1995 and 2008, reaching 25% by 2008.

¹⁵Employment, payroll and sales receipts variables are not collected by the SBO but instead merged by the Census Bureau from the economic censuses conducted in parallel to the SBO.

pay lower wages (measured as payroll divided by employment), with an 12% differential evident in 2012, and begin with more start-up capital.

Looking at the traits of entrepreneurs, female ownership is similar across both firm groups. Immigrant entrepreneurs tend to be younger and are more likely to combine owners of several ages, perhaps indicative of a greater prevalence of family businesses. Education levels are broadly comparable between immigrants and natives. Native-only firms are more likely to have single owners, while firms with immigrant or mixed owners are more likely to report three or more owners.

In addition to paying lower wages, immigrant-owned firms are less likely to offer employee benefits such as health insurance, retirement benefits, and paid leave. These differences across owner types are among the starkest in the SBO data and perhaps indicate less attractive employment. (The provision of these benefits declined among all start-ups between 2007 and 2012, which we have confirmed in other data sources like the Current Population Survey.)

Immigrant-owned firms are comparable to native-owned firms in terms of hiring temporary versus full-time workers. Nationally, temporary workers account for just over 2% of private sector jobs (Economics and Statistics Administration, 2015). Temporary employment includes workers from temporary agencies, day laborers, and leased employees; part-time workers are a separate category. Finally, immigrant-owned firms show a much higher rate of international activity as measured by exporting, outsourcing, and maintaining overseas operations.

Table 1b separates purely immigrant-owned start-ups from mixed teams, with Appendix Table A1b providing comparable breakouts for all firms. Immigrant-only teams accounted for 19% and 22% of new firms in 2007 and 2012, while mixed teams accounted for 5% and 4%, respectively. Start-ups with mixed ownership tend to be larger and begin with more capital, but they are comparable for wages and receipts per employee. Interestingly, the most common number of owners is two for mixed teams, as compared to only one among immigrant- and native-only firms. The greater number of owners allows for mixed teams to show more ownership diversity for age, education, and gender. With respect to benefits, mixed-owner firms are more likely to offer health insurance and paid leave, but not retirement benefits. Related to hiring more employees, mixed-owner firms are more likely than native-only firms to hire both temporary and full-time workers. Lastly, mixed-owner firms report international operations at a higher rate than any other firm group, including immigrant-only firms.

Table 1c considers new firms in high-tech vs. low-tech industries. Immigrant-owned startups comprised 29% and 26% of high- and low-tech entry in 2012, respectively. This is similar to 2007, but rates among high-tech firms rose faster (the proportions were 25% and 24%, respectively). Among immigrant-owned firms, high-tech firms tend to hire fewer employees and pay almost double the wages of immigrant-owned firms in low-tech settings. Start-up capital amounts are consistently lower among high-tech firms, but higher for immigrant-owned firms among both groups.

High-tech firms often have larger founding teams, despite their lower employment, but are less likely to include women. High-tech founders are also more concentrated in higher levels of education. High-tech firms are substantially more likely to offer benefits and engage in international activities. The earlier differences among immigrant- and native-owned firms remains among both industry groups in regards to international operations; differences in employer-provided benefits remain for low-tech firms but are much smaller for high-tech firms. As noted earlier, this could be due to the prevalence of high-tech firms in more competitive markets for employees.

3.3 Industry, Financing and Geographic Variation

Table 2 lists the most common two-digit NAICS industry codes for immigrant- and native-owned firms. Roughly half of immigrant-owned startups are in three sectors: accommodation and food services, retail trade, and professional and technical services. Native-owned firms show less industrial concentration, as noted earlier. This industry breakdown highlights the concentration of immigrant entrepreneurs at the upper and lower ends of the distribution. Professional and technical services include many high-tech industries, whereas accommodation and food services and retail trade fall into the low-tech category.

The differences in firm traits in Tables 1a-1c could be due to these industry choices, but data from the March 2017 National Compensation Survey conducted by the Bureau of Labor Statistics suggest that industry differences are unlikely to bear full responsibility. Our working paper tabulates in greater depth how the three most prominent sectors for immigrant-owned businesses fall above and below national averages on most dimensions like offering benefit plans. Upcoming regression analyses control for industry differences in a rigorous manner.

Previous studies document that immigrant-owned businesses start with more funding (e.g.,

Fairlie 2012); the 2007 SBO shows that much of this difference comes through firms with mixed ownership teams. Table 3 shows the most common sources of start-up capital for immigrant entrepreneurs.¹⁶ The first panel reports capital sources for all new firms, while the second two separate firms by industry. Firms with mixed owners report a higher use of nearly all funding sources. Personal savings are the most important source of capital for all firms, but this source is especially important for firms with immigrant owners. Firms with native owners are more likely to have bank loans and credit, while those with immigrant owners are more likely to rely on family loans. The use of home equity is highest among mixed owner firms and fell across all groups between 2007 and 2012, reflecting the effects of the Great Recession. These patterns may signal a lower ability by immigrants to obtain bank credit.¹⁷ Venture capital funding is rare but consistently higher for high-tech firms.

Figure 1 documents the states with the greatest and least reliance on immigrant entrepreneurs, with extreme values tabulated in Table 4. The least dependent states, such as Montana, the Dakotas, and Idaho, have 6% or less of their new firms founded by immigrants in 2012, whereas the shares for California, New Jersey, and New York exceed 40%. These differences are naturally tied to geographic variation in where immigrants make up a large share of the population. The correlation in 2012 between the working age population share and firm owner share for immigrants is 0.85 for new firms and 0.91 for all firms. Metropolitan areas within states also vary substantially. The most-dependent MSAs in California display immigrant business owner shares in excess of 60%, a 50% increase upon the state average.

Figure 2 illustrates the absolute growth of immigrant entrepreneurship by state between the 2007 and 2012 SBO. Texas (6%), New Jersey (6%), and Alabama (5%) saw the largest gains, while the District of Columbia (-10%), New Mexico (-5%), and South Dakota (-3%) saw the largest declines. Figures for some of these smaller states should be treated with caution given smaller sample size. Most states experienced modest increases, while 15 states saw a decline, in the percent of new firms founded by immigrant entrepreneurs between 2007 and 2012.

Figure 3 plots the share of immigrant entrepreneurs among high-tech vs. low-tech startups by state in 2012. The included 30 states in the graph are those where a sufficient number of

¹⁶Appendix Table A2 shows similar patterns for sources of expansion capital, with native-only firms being less likely to expand.

¹⁷For example, Blanchflower et al. (2003), U.S. Chamber of Commerce (2005) and Bruder et al. (2011).

SBO observations pass the Census Bureau’s disclosure rules for both industry groups. Most states are clustered around the 45-degree line, reflecting a similar proportion of immigrant entrepreneurship across industries, and the correlation of the two series is 0.83. The main outlier is New Jersey, which had more than 60% of new, high-tech firms founded by immigrants in 2012.

4 Regression Analysis of Immigrant Entrepreneurs

Our descriptive tabulations measure sizable differences between immigrant- and native-owned firms in terms of employment, wages, and other job characteristics like employer-provided benefits. This section analyzes the degree to which these differences persist once we control for state and industry choices, along with other observable traits of the owners like age, gender, and race/ethnicity. The background regression takes the form:

$$Y_{f,t} = \beta \cdot \text{Imm.Entr}_{f,t} + \zeta \cdot \text{Mixed.Entr}_{f,t} + \gamma X_{f,t} + \delta_t + \varepsilon_{f,t}, \quad (1)$$

where $Y_{f,t}$ is a measured trait of the firm. $\text{Imm.Entr}_{f,t}$ takes a (0,1) value for the founding team being comprised exclusively of immigrants. $\text{Mixed.Entr}_{f,t}$ take a (0,1) value for the founding team being comprised of both immigrants and natives. Native-only teams serve as the reference category.

Our regression models combine the 2007 and 2012 SBO data and control for year fixed effects δ_t . Baseline controls $X_{f,t}$ include the firm’s state and six-digit NAICS industry, and the gender, age, and number of owners of the firm. These controls are incorporated through indicator variables. We also consider ethnicity by aggregating baseline SBO categories into three groups: African-American, Hispanic (Mexican, Cuban, Other Hispanic, not Puerto Rican), and Asian (Chinese, Indian, Filipino, Japanese, Korean, Vietnamese, and Other Asian). We then enter for each of these groups the share of founders who are of that ethnic background. In a second regression set, we further add a control for the log of firm employment as a size measure.

Figure 4 reports the β point estimates and confidence intervals for the indicator variable of an immigrant-only founding team. Regressions are unweighted and use robust standard errors to derive 95% confidence intervals. To facilitate easy comparison, we conduct these regressions separately for high-tech vs. low-tech firms and combine the results into Figure 4. Circles in-

dicating the coefficients for immigrant founders in high-tech entrepreneurship; triangles indicate the same for low-tech industries. The accompanying table reports the relative economic magnitude of the coefficient for immigrant entrepreneurs. This effect is calculated as the coefficient divided by the mean of the outcome variable. These calculations help evaluate the relative economic magnitudes given that some outcomes are in logs (the first four rows) vs. indicator variables (the rest); they also account for baseline differences across industries.¹⁸

Panel A displays the results without firm size controls. Immigrant entrepreneurs hire fewer employees than native-owned firms, with a sizable relative effect of 16% for low-tech sectors. The immigrant effect is smaller at 5% and not statistically significant for high-tech firms. By contrast, immigrant vs. native founder differences on start-up capital raised, labor productivity (i.e., receipts/employee), and wages tend to be quite modest and with a relative effect of under 1%. The types of employees hired by immigrant-only founders look mostly similar to their native peers.

The more noticeable differences are at the bottom of Panel A. Immigrants in low-tech settings are substantially less likely to have employer-provided benefits, with the relative size ranging from 24% less for paid time off to 66% for 401k plans. As a summary metric, immigrant startups in low-tech sectors are 18% less likely to offer any of the three indicated employer-provided benefits than natives. Within the high-tech industries, the gaps are substantially less, but still reach a 16% relative effect for the offering of 401k plans. In total, immigrant-only high-tech startups are 4% less likely to offer any of the three indicated employer-provided benefits than natives. Thus, the average “job quality,” as defined by these metrics, is weaker in immigrant-owned firms, and the earlier analysis shows that the lower provision of these benefits is not being offset in higher wages.

Similarly, but in the opposite direction, immigrant-owned startups show typically 40%-70% increases in international engagement. These international engagement effects are less distinguishable between low-tech and high-tech firms. In aggregate, immigrant founders in low-tech and high-tech sectors are 81% and 57%, respectively, more likely to engage in one or more of the three forms of international engagement captured by the SBO.

While we do not report the regression coefficients for control variables, a few results are

¹⁸Tables A3a-A4n in the online appendix provide our complete estimations. These tables also provide analyses with a full sample combining high-tech and low-tech together, regression variants without control variables, and regression variants where we do not parse out the mixed ownership group. Our NBER working paper also contains additional variations of these regressions.

worth noting. Startups with more owners tend to hire more workers, start their firms with more capital, pay higher wages, and are also more likely to provide employee benefits. Larger firms, in general, are also more likely to pay better and to offer employee benefits. Part of this difference is due to legal mandates imposed upon larger firms, but a long literature has noted the greater general attractiveness of jobs in larger firms (e.g., Moore 1911; Brown et al. 1990; Gibson and Stillman 2009). Firms with female owners, younger owners, and lower-educated owners tend to hire fewer employees, pay lower wages and benefits, and engage less in international activities.

In most cases, these estimated coefficients and effects in Figure 4 resemble what is observed in tabulations of the raw data; we also tend to find similar results (tabulated in the appendix) when excluding all firm controls $X_{f,t}$. One of the more interesting exceptions is that the lower wage rates paid by immigrant firms in the low-tech sector would be more significant at 1%-1.5% in relative terms without the controls, compared to the 0.2% with the controls. State and industry choices account for about half of the difference, and adding ethnicity controls accounts for the rest, with Asian and Hispanic owned firms paying lower wages in the low-tech sector.

Panel B introduces the firm size control. It is debatable whether one should control for the fact that immigrants tend to own different-sized firms than natives, as we use firm size in constructing some metrics (e.g., receipts per employment) and the size of a company is endogenous with other firm outcomes. Nevertheless, the overall picture remains very similar. For most firm traits, this control slightly diminishes the coefficients and relative magnitudes, but the major themes of weaker provision of benefits and greater overseas activity persist.

Figure 5 plots regression coefficients similar to Figure 4 for a variant of specification (1) that combines the immigrant only and mixed team indicator variables. Most of themes emphasized above are reproduced, as the number of mixed ownership teams is small compared to the immigrant only count. The most noticeable differences are a moderating effect on the observed lower provision of employer-provided benefits by immigrant owned companies and an expansion of differences compared to native only firms for international engagement.

Finally, Tables 5a and 5b study the survival and growth properties of immigrant- vs. native-owned firms using the subsequent history of 2007 SBO firms to 2011 in the LBD. The sample begins with 139 thousand companies that were founded between 2002 and 2007 and present

in the 2007 SBO. Among those firms matched to the 2007 LBD, immigrant-only founded firms are somewhat more likely to survive to 2011 than are native-owned firms (62.8% versus 60.1%). Conditional on survival until 2011, immigrant-only firms remain somewhat smaller than native-only firm, with immigrant-only startups growing their employment 23% to 2011 versus 19% for natives.¹⁹

As we parse the sample into high-tech vs. low-tech, interesting differences emerge. The survival rate for immigrant-only high-tech startups tends to be equal to or less than native-only firms, but the growth rate is significantly faster in large part due to a smaller starting size. For low-tech, immigrant-only firms are more likely to survive and again appear to catch-up in terms of employment by 2012 to native-only firms.

Table 5b shows the stability of these patterns in regression formats, using linear probability models for survival. In aggregate, immigrant-founded firms in high-tech behave in a manner quite similar to native-founded high-tech firms, whereas differences for low-tech remain conditional on size. The faster growth of immigrant-owned firms in both samples directly connects to their smaller starting size. The 2007-2011 period was, of course, the depths of the Great Recession, and with the future extensions of the LBD it will be important to look at these patterns throughout the subsequent recovery.

5 Extensions

5.1 Spatial Differences

We earlier noted that immigrant entrepreneurship is unevenly distributed across the country, with eight-fold or higher differences across states. Florida (2005), Moretti (2012), and other scholars emphasize the growth of powerful high-tech and knowledge centers, with spillover effects onto job creation for other workers. The authors frequently connect these dynamic clusters to immigration and entrepreneurship, and many business press accounts speak of a Silicon Valley exceptionalism. We turn to describing with new data the role of immigration entrepreneurs across tech hubs.²⁰

¹⁹We define growth through the log ratio of 2011 employment to 2007 employment, and the patterns are very similar if instead using the Davis et al. (1996) formula with average employment as the baseline.

²⁰In addition to providing an economic portrait of current activity, these distributions can be informative for potential policy changes to encourage regional visas for incoming skilled immigrants. Such visas are used, for example, in Canada and are often discussed as a mechanism for building broader policy consensus around expanded migration.

Table 6 describes how immigrant entrepreneurs are distributed over MSAs. While 29% of new high-tech firms are owned by immigrants or mixed teams, this share is 63% in the San Francisco Bay area and 44% in other top tech clusters, compared to 18% elsewhere. Dramatically, about 4% of all high-tech firms owned by immigrants are located in the San Francisco Bay area, compared to 1% for natives. New immigrant-founded firms also constitute high shares of low-tech activity in the big tech centers, but there is overall more mass of immigrant low-tech startups outside of the top 10 tech clusters.

Figure 6 maps regression coefficients for immigrant-only, mixed, and native-only founding teams by location, with native-only founding teams located outside of the top 10 tech clusters serving as the reference group. Appendix Table 6 provides the underlying regressions. Panel A of Figure 6 shows that high-tech firms founded by immigrants only are modestly under-sized relative to their peers in the top 10 tech clusters, but the bigger differences are in the low-tech sector where immigrant-only startups are smaller within and outside of tech centers.

The remaining panels of Figure 6 condition on firm size in addition to the other controls. For startup financing, immigrant-only teams raise more seed capital within and outside of the top tech clusters, whereas no real difference exists for low-tech sectors. On receipts per employee, immigrant-only teams look mostly similar to their native-only counterparts, while wages paid by immigrant-only firms are lower in high tech clusters than peer companies. Lower provision of employer-provided benefits by immigrant-only firms is most pronounced in low-tech sectors, regardless of spatial position, and the gap is erased in mixed teams. By contrast, the greater propensity by immigrant founders towards international activities is strongest in high-tech sectors and independent of a mixed or immigrant-only founding team.

We interpret these results as suggesting that most of the impact of immigrant high-tech entrepreneurship for tech centers happens through the quantity dimension: Silicon Valley and similar tech hubs attract a lot of immigrant founders. Being located in a high-tech cluster demands more of companies: higher receipts per employee and greater wages. Immigrant-founded firms are not very different on these dimensions, providing slightly lower wages and benefits, as we have seen in prior analyses. This is somewhat to be expected: when representing 40% or more of local startups, it is harder for immigrant founders in tech clusters to behave too differently from peer entrants.²¹

²¹Earlier versions of this paper considered generic state-level policies like minimum wages and occupational licensing, finding little explanatory power. Interesting for future research, an index developed by Monogan

We supplement this SBO analysis with comparable evidence from the publicly available American Community Survey (ACS) data. Within the ACS, the closest metric to business ownership is self-employed individuals in incorporated businesses (SE-I). The primary ACS sample is restricted to individuals who report their place of birth and are aged between 25 and 55. The ACS shows that an increasing share of SE-I entrepreneurs are immigrants, growing from 17% in 2001 to about 24% by 2015.²²

Table 7 again shows immigrant SE-I are disproportionately agglomerated in top tech hubs compared to native SE-I. While the ACS collected fewer data fields, we can look at income levels reported for the individual and household. Interestingly, immigrant SE-I in high-tech industries report mostly comparable income to native SE-I in all geographic settings. By contrast, low-tech immigrant SE-I report lower incomes than native SE-I and these differences become more pronounced in leading tech hubs, as the incomes for native SE-I rise faster. These intriguing patterns suggest that immigrants engaged in high-tech entrepreneurship in the prominent tech hubs are quite similar to their native peers, but that these larger cities also have a more expansive low-tech immigrant entrepreneurship sector that behaves differently from native-led startups nearby in these sectors.

5.2 Second-Generation Immigrant Entrepreneurs

The SBO data allow the identification of individuals who were born in the United States but are of a specific ethnic origin, including Chinese, Indian, and Mexican. While the survey does not ask whether one or both their parents were born outside of the United States, one can approximate second-generation immigrants via ethnicity. Using the public use ACS data for 2001-2016, we find that 94% of U.S.-born persons who report to be of Chinese ethnic origin have at least one parent who is an immigrant. These percentages are 99% and 71% for persons of Indian and Mexican ethnic origin, respectively. Table 8 repeats the earlier tabulations in

(2013) to quantify the state-level “tone of immigrant policy” enacted between 2005 and 2011 can predict higher immigrant entrepreneur shares over-and-above the immigrant population baseline. This index captures features like the ability of immigrants to obtain an ID or drivers license to enforcement activities by U.S. Immigration and Customs Enforcement. A one standard-deviation in policy tone predicts a 1-2% increase in immigrant founder shares.

²²Similar to Figure 2, most states show growing immigrant SE-I shares across this time period, with 14 states exceeding 6% growth, while only three states—West Virginia, Vermont, and Maine—saw declines. Immigrant SE-I has pulled increasingly from individuals coming from Mexico, India, and China since 2001, although no country accounts for more than 4% of the total SE-I stock in 2015. In 2015, immigrant SE-I shares are higher for those with STEM degrees (27%) or Business/Education (22%) compared to other fields (17%). Our NBER working paper provides additional statistics related to this sample.

Table 1a but separates out the entrepreneurial activity of second-generation immigrants to the United States. We identify these individuals as those labelling themselves as born in America but of an immigrant ethnicity. These labels are imperfect, to be sure, but also provide a reasonable approximation on a phenomenon of broad interest.²³

For these tabulations, Columns 1 and 4 report statistics where only first-generation immigrants are owners of the business, potentially along with natives, but no second-generation immigrants own the business. Columns 2 and 5 focus only on businesses where second-generation immigrants are owners, potentially along with natives, but no first-generation immigrants are owners. Columns 3 and 6 document cases where only natives are owners. As such, the columns are mutually exclusive but not collectively exhaustive. In particular, about 1% of the sample is not included and represents cases where both first- and second-generation immigrant business ownership is reported for the firm. With this framing, second-generation immigrants account for approximately 4% of U.S. entrepreneurship in 2007 and 6% in 2012.

A fascinating pattern emerges: on many dimensions where the differences between immigrant- and native-owned firms are most visible (e.g., offering health insurance, exporting), businesses owned by second-generation immigrants sit in between the other two firm types. This patterns highlights a potential assimilation of immigrant-founded firms into the broader business landscape of America which has not been documented before.²⁴ Second-generation immigrant owners tend to be younger than the other owner types, which may, for example, affect their ability to accumulate start-up capital. Female-owned firms (whether fully or partially) are most common in the group of second-generation immigrant-owned companies, in both the newly founded and all firms samples.

²³Duncan and Trejo (2018) review the evidence regarding second-generation immigrants in the United States, their education assimilation, and the heterogeneity across countries of origin, but entrepreneurship remains under explored. Case examples include Waters (1994), Zhou and Bankston (1994), and Berry et al. (2006). Data from the 2012 Global Entrepreneurship Monitor (GEM) indicate that US first-generation immigrants are more entrepreneurial than either natives or second-generation immigrants (Kelley et al. 2012). Looking at Fortune 500 companies in 2011, roughly equal proportions of them were founded by first-generation (19%) and second-generation (23%) immigrants (Partnership for a New American Economy 2011). Andersson and Hammarstedt (2010) study the self-employment activity of second-generation immigrants in Sweden, and Beckers and Blumberg (2013) consider the Netherlands. While the SBO cannot quantify rates of entry into entrepreneurship by first- versus second-generation immigrants, the data allow us to describe their businesses.

²⁴It important to note that the assimilation interpretation cannot be distinguished with these data from cohort effects. The SBO second-generation entrepreneurs are children of first-generation immigrants from an earlier cohort, who came from different places and under different contexts than the first-generation immigrants of today. To fully untangle, future work needs access to data sources like the Internal Revenue Service that directly link second-generation children to their immigrant parents.

6 Discussion and Future Research

We explored the 2007 and 2012 Survey of Business Owners records to learn more about how the businesses created by immigrants resemble and differ from those owned by natives. To summarize a few key findings: immigrant-owned firms are somewhat smaller than native-owned firms in terms of employee counts but have comparable or greater sales per employee; the jobs created by immigrant firms have mostly comparable salaries but lower provision of health, retirement, and paid time off benefits; and the firms owned by immigrants show a substantially higher rate of engagement in international activity like exporting and the launch of overseas facilities. Immigrant-owned businesses have a modestly different industry composition than native-owned business, but the bigger differences are spatial, with ten-fold differences across states in terms of the share of businesses owned by immigrants. Finally, new immigrant-owned businesses in the 2007 SBO are more likely to survive to 2011 and show greater employment growth to 2011.

There are several important directions future research can take. We have provided novel evidence on the quality of jobs generated by immigrant-owned firms in terms of compensation and benefits, but there many other dimensions worth pursuing. Merging onto the SBO the Longitudinal Employer Household Dynamics (LEHD) database would allow researchers to look at the duration of jobs and the evolution of earnings over tenure for workers in immigrant-versus native-owned firms. The LEHD's mostly universal nature would also allow a greater characterization of ethnic enclaves within regions and how immigrant entrepreneurs function inside vs. external to them.

Uniting the Decennial Census files with the SBO data would also provide greater information on the countries of origin of immigrants. These extra data would allow researchers to examine more sharply differences over groups. As immigrant entrepreneurship rates differ somewhat by nationality, one could learn more about how much of these patterns follow from group-wide preferences to be one's own boss (Hurst and Pugsley 2011) and how the concentration of immigrant groups into specific occupations for entrepreneurship (Kerr and Mandorff 2015) shifts their behavior. Such extensive margin evidence would better highlight the mechanisms behind perceived differences in job quality.

The evidence regarding greater overseas activity of immigrant-owned businesses also deserves more consideration. These contributions may be more quantitative and model-based:

what are the general equilibrium implications of a rising share of U.S. entrepreneurs being immigrants and therefore being more likely to engage in global activities? As the period of time covered by these surveys includes some countries expanding and others contracting, the relative value of these overseas connections will provide nice variation to tease out their empirical effects.

Finally, we have provided some basic evidence and back-of-the-envelope calculations for job provision in immigrant firms in the introduction, but more of the job creation and job destruction machinery (e.g., Davis et al. 1996) and growth analysis (e.g., Puri and Zarutskie 2012) could be applied to these groups. This would be especially powerful when combined with information on the individuals hired. Immigrant owners may show different employment adjustment patterns for immigrant employees from their home country than immigrants from other countries or native employees. Given the heavy geographic and industrial clustering of immigrant entrepreneurs, this could in turn influence regional business cycles.

Figure 3: Immigrant entrepreneur distribution in high-tech vs. low-tech sectors in 2012

Notes: See Figure 1. Sample includes 30 states for which the number of firms is above the Census Bureau's disclosure cut-off for both high-tech and low-tech sectors. The correlation across series is 0.83.

Figure 4: Estimations for firm traits of immigrant entrepreneurs

Panel A: Baseline controls

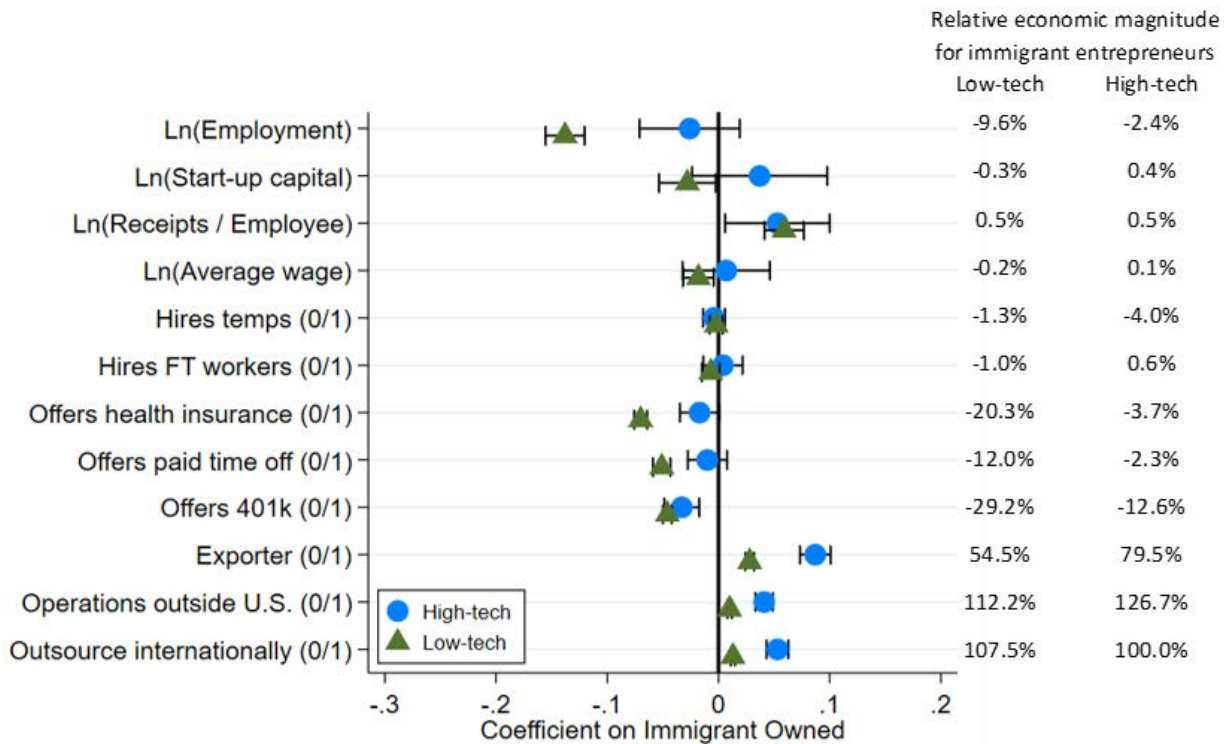

Panel B: Baseline controls plus firm size control

Notes: See Figure 1 and Table 1a. Estimations pool 2007 and 2012 data. Coefficients are from an indicator variable for Immigrant only owners. Panel A includes fixed effects for year, state, and 6-digit industry and controls for the gender, ethnicity/race, age, and number of owners. Panel B further controls for log employment. Regressions are unweighted and show 95% confidence intervals based upon robust standard errors. Appendix Tables A3a-n tabulate results. Relative economic magnitudes are calculated as the ratio of the regression coefficient and the mean of the dependent variable.

Figure 5: Figure 4 combining Immigrant only and Mixed teams

Panel A: Baseline controls

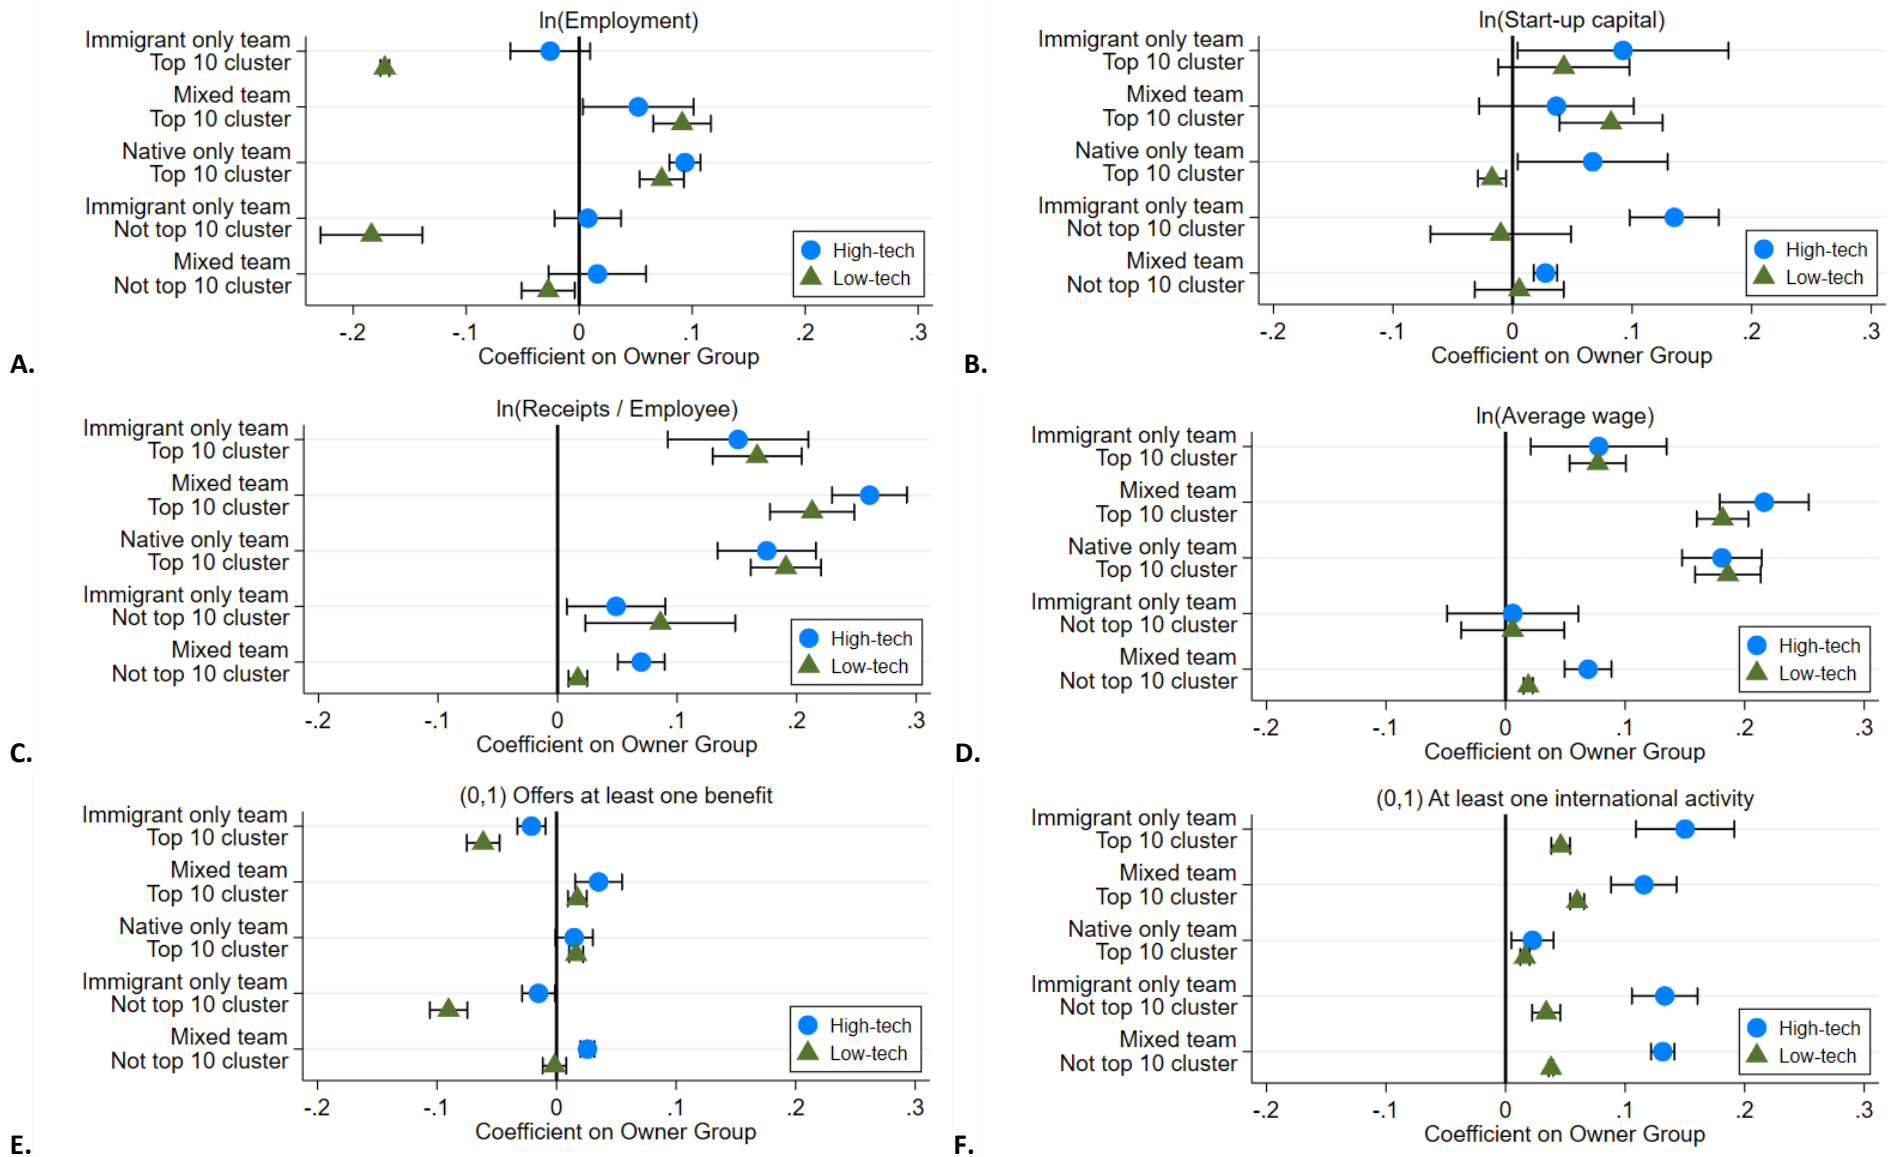

Panel B: Baseline controls plus firm size control

Notes: See Figure 4. Coefficients are for an indicator variable which combines Immigrant only and Mixed firm ownership. Appendix Tables A4a-n tabulate results.

Figure 6: Geographic and industry interactions

Notes: See Figure 4. Firms are separated by ownership types, geographic location, and high-tech vs. low-tech sector. The reference group in estimations is Native only firms located outside of Top 10 clusters. Figure A includes all controls except firm size. Firm size is added as a control for Figures B-F. Appendix Table A6 provides detailed results.

Table 1a: Summary statistics for immigrant and native entrepreneurship

	2007		2012	
	Immigrant/Mixed	Native only	Immigrant/Mixed	Native only
	1	2	3	4
% of firms	23.7%	76.3%	26.0%	74.0%
Mean: employees	5.26	5.45	5.03	5.88
Mean: employees if >0	6.57	6.91	6.52	7.70
Mean: receipts (thousands)	\$739	\$729	\$752	\$839
Mean: ln(receipts/employee)	11.44	11.34	11.51	11.38
Mean: payroll/employee	\$27,720	\$31,350	\$28,470	\$32,290
Mean: start-up capital	\$164,900	\$136,900	\$146,800	\$126,800
% 1 owner	48.5%	49.9%	59.7%	61.6%
% 2 owners	37.9%	38.9%	28.8%	29.0%
% 3 or more owners	13.6%	11.2%	11.5%	9.4%
% female owners	48.3%	47.3%	44.1%	44.1%
% owners < 35	12.9%	14.5%	13.0%	15.5%
% owners 35-55	58.9%	54.0%	58.5%	50.9%
% owners > 55	10.1%	14.9%	12.1%	18.7%
% mixed age	18.0%	16.6%	16.4%	14.9%
% high educated	41.9%	42.1%	46.0%	49.1%
% low educated	44.4%	42.6%	42.7%	38.7%
% mixed educated	13.6%	15.4%	11.4%	12.2%
% offer health insurance	24.2%	33.9%	18.6%	26.4%
% offer 401k	9.7%	15.5%	8.4%	12.5%
% offer paid leave	33.1%	38.8%	28.4%	34.6%
% hire temps	10.3%	11.0%	6.8%	5.9%
% hire full-time workers	69.3%	67.1%	62.5%	60.5%
% export	8.3%	4.7%	6.9%	2.6%
% outsource	2.7%	0.9%	3.1%	1.2%
% operations abroad	1.5%	0.5%	2.7%	1.1%
% in high-tech industry	11.8%	11.1%	15.7%	13.7%
SBO survey size (rounded)	30,000	109,000	12,000	36,000

Notes: Sample includes non-public employer firms, with entrepreneurship measured as new firms created in the five years prior to the survey. Data for 2007 use noise infusion for employment, receipts, and payroll, as well as variables derived using those measures. Reported numbers use tabulation weighting and are rounded to maximum of four significant digits. Groupings: Immigrant only includes firms with only immigrant owners, Mixed includes firms with both immigrant and native owners, and Native only includes firms with only native owners. Immigrant only and Mixed are combined in this table.

Table 1b: Table 1a splitting Immigrant only and Mixed founding teams

	2007			2012		
	Immigrant only	Mixed	Native only	Immigrant only	Mixed	Native only
	1	2	3	4	5	6
% of firms	18.5%	5.2%	76.3%	21.7%	4.3%	74.0%

Notes: See Table 1a. Data for 2007 and 2012 are pooled. Regressions are unweighted. Immigrant only and Mixed firms presented separately. High-tech is defined as belonging to a high-tech or patent-intensive industry, as described in the main text. Control variables are entered through indicator variables. Robust standard errors are reported.
